

PENICILLIN IN SUBACUTE BACTERIAL ENDOCARDITIS

REPORT TO THE MEDICAL RESEARCH COUNCIL ON 269 PATIENTS TREATED IN 14 CENTRES
APPOINTED BY THE PENICILLIN CLINICAL TRIALS COMMITTEE

BY
Professor DONALD V. CHRISTIE, M.D., D.Sc., F.R.C.P.
Secretary of the Committee

January, 1945, and March, 1946. 269 patients with subacute bacterial endocarditis were treated as appointed by the Medical Research Council in 14 centres: Bristol, Edinburgh, Liverpool, London (St. Mary's), Middlesex, New's Hospital, Manchester, Newcastle, Sheffield. All patients were unselected, diagnosed and treated according to a

83 patients receiving 250,000 units a day for 28 days, 13 (16%) relapsed or died infected. Of 58 patients who received 500,000 units a day for 28 days, 4 (6.9%) relapsed or died infected. Only occasionally can failure be explained on the basis of a highly resistant organism; in the four failures referred to above the coefficient of resistance was expressed as a multiple of that of the Oxford staphylococcus was 2, 2, 6, and 32.

Only two previously untreated patients received other systems of dosage, and the results in this group, although the not instructive from a therapeutic point of view, are shown in Table 1:1.

Results in Previously Untreated Cases

Investigation was planned not only was but very few cases of recovery had been or these organisms of penicillin were now known to be adequate.

Of 52 patients with a total of 5 million daily dosage was used (Table 1). Thus experi-

Received a Total of 5 Million Units of Penicillin, of 5, and 20 mg. (No case had previously received penicillin)

Treated	Died with Infection Apparently Controlled	Infection Uncontrolled	Relapsed	"Cured"	Average Follow-up (Days)	Relapsed or Died Infected
18	1	2	13	0	665	83%
16	4	0	4	25%	579	50%

0.5 mega unit for 2 weeks, increased to 1 mega unit for 2 weeks	4		1		3

Except in a few cases penicillin hourly injection or by continuous (946) found that a peptide which No difference in the therapeutic crystalline proteins, including strated, and opinion on the potential for the growth of haemolytic divided. In some cases try also for the growth of mice in mately as stated: these essential amino-acids plus glycine. He previous report in the "strepogenin." Strepogenin is present 1946 (p. 381). Polysates but not in acid ones.

Urinary Leakage after Injections

Patients who his colleagues found that, soon after giving with regard acids intravenously, substantial amounts were patients who eted in the urine; the excretion was less when 59% again given by the skin and least by mouth. Clinicians calculated even by the skin and least by mouth. Clinicians not previous America have found that large amounts of have been in the urine in the first half-hour or so after who re polysates by vein. The losses can be detected to the appearance and smell of the urine. This raises to a portant question whether, in normal absorption (Take intestine, amino-acids undergo any change in 1 or chemical properties in passing through the al wall and the liver. It may be that the epithelium

to amino-acids and peptides. The body is intolerant of foreign proteins, and if they get into the blood they cause reactions of an anaphylactic type. Human blood can, however, be given by vein with impunity.

This evidence, provided mainly by Madden and Rose (1940), that blood proteins can supply the "building" required for the construction of the body's protein for long it was assumed that the amino-acids, if absorbed, went via the portal vein to the liver, where those not wanted by the body were de-aminized to a non-nitrogenous residue used for energy, while the rest was used for growth or repair by any organ or tissue picked up from the general circulation. Whipple, on the basis of much experimental evidence, has advanced a new theory about the fate of absorbed amino-acids and peptides. It is that (a) the amino-acids are absorbed mainly in the liver, into plasma proteins; (b) there is a constant ebb and flow between plasma and tissue; (c) in the tissues there is a reserve store of amino-acids for emergency use; and (d) normally a state of equilibrium exists between the plasma proteins, tissue proteins, and those ingested.

Proteins.—It would follow from Whipple's theory that we have had, since blood transfusion became a means of supplying by vein all the proteins the body requires; but it is doubtful if supplies of human plasma are available, or likely to be available in the near future, would suffice for the very many uses to which plasma could be put in intravenous alimentation. However, we do not know whether plasma proteins can be used for energy purposes. As I point out later, a large portion of the energy needs of the patient treated by intravenous alimentation must, in the present state of knowledge, come from the proteins injected. The use of plasma is therefore likely to be confined to the purposes for which it was originally intended—namely, to combat shock and the effects of haemorrhage and of certain diseases.

Protein Hydrolysates.—Loewi in 1902 was evidently the first to show that nitrogen equilibrium and weight could be maintained by administering protein digests by mouth. He fed dogs on pancreatic digests of protein, plus starch and fat. In 1913 Henriques and Andersen kept goats in weight equilibrium for twenty days with intravenous protein digests, sugar, and salts. In 1938 Rose showed that ten of the thirty or so known amino-acids, given by mouth as the only source of N, sufficed for maintenance of N balance and weight in rats. The practical significance of these findings did not become apparent until Elman and Weiner (1939) reported the successful administration of protein digests by vein to human patients. Since then increasing attention has been paid to the subject, and there are at present on the market American and British hydrolysates of proteins, which can be given to human patients day after day in substantial quantities without reaction and often with striking success. The subject has been reviewed by Cuthbertson (1944), Cuthbertson (1944), and Gaunt (1944).

Hydrolysis of protein can be effected by acids or by enzymes, but enzymic preparations have been found to be the more successful. The earlier preparations often provoked reactions which were caused, as animal experiments showed, either by toxic substances produced by bacteria or by large polypeptide aggregates. The enzymic preparations now used very extensively in North America seem to be practically free from such risks and less prone to cause digests to cause thrombosis. An enzymic preparation made in this country, and at present being subjected to an extensive trial under M.R.C. auspices, appears

also to be giving satisfactory results, but further experience must be gained before its full therapeutic value can be stated.

Amino-Acids

Madden and Whipple (1946) have done much experimental work on dogs to ascertain whether solutions of pure amino-acids given parenterally could maintain the animals in N equilibrium. The work of Rose (1938), showing that only ten amino-acids are essential, simplified the trials of Whipple's school. He was able to secure substantial quantities of these amino-acids, most of them synthetically prepared, and showed that, when given by mouth, skin, vein, or peritoneum along with glucose, they sufficed for N equilibrium, but weight was not wholly maintained. Whipple, when I saw him in his laboratory in October, 1946, expressed the opinion that another protein element, perhaps a peptide, is essential for health, and it may well be the strepogenin of Woolley (1946); I will take this up later.

All synthesized amino-acids are in racemic form—i.e., a mixture of the natural and unnatural isomers. The animal body can make use of only the natural isomers, and the unnatural forms, which Madden and Whipple (1946) and Madden *et al.* (1946) found to be non-toxic to man, however administered, are excreted unchanged by the urine. The ten essential amino-acids are: threonine, valine, leucine, isoleucine, lysine, tryptophan, phenylalanine, methionine, histidine, and arginine. The use of mixtures of these on an extensive scale is out of the question; they are difficult and very costly to manufacture.

Rose *et al.* (1942, 1943), who maintained young men for several weeks on a diet of which the N was in the form of amino-acids, are of the opinion that arginine and histidine are less essential for man than for the other animals tested. Madden, Whipple, *et al.* (1945) have always incorporated glycine in the amino-acid mixture given to human patients because this seems to make it better tolerated. They have reported the maintenance of, and even gains in, weight of several patients suffering from various diseases with mixtures of the ten essentials and glycine given by vein, skin, or mouth, plus small amounts (about 7 g.) of protein by mouth. It may well be that the protein consumed by mouth filled the part of strepogenin in the animal experiments. One patient suffering from ulcerative colitis was kept going in this way for 100 days, during which a gain in weight of 11 kg. occurred (Madden *et al.*, 1946).

Strepogenin.—Woolley (1946) found that a peptide which he isolated from certain crystalline proteins, including insulin, and which is essential for the growth of haemolytic streptococci, is necessary also for the growth of mice in addition to the ten essential amino-acids plus glycine. He called the peptide "strepogenin." Strepogenin is present in enzymic hydrolysates but not in acid ones.

Urinary Leakage after Injections

Whipple and his colleagues found that, soon after giving amino-acids intravenously, substantial amounts were rapidly excreted in the urine; the excretion was less when they were given by the skin and least by mouth. Clinicians here and in America have found that large amounts of N are lost in the urine in the first half-hour or so after giving hydrolysates by vein. The losses can be detected even by the appearance and smell of the urine. This raises the important question whether, in normal absorption from the intestine, amino-acids undergo any change in physical or chemical properties in passing through the intestinal wall and the liver. It may be that the epithelium

renders the amino-acids more easily metabolized or convertible into plasma proteins. Kotschneff (1926) claims to have found in dogs an increase in polypeptides in the portal vein during absorption of protein meals and of amino-acids. The findings of Madden and Whipple (1946), showing that amino-acids given orally result in better production of blood proteins than when given by vein, support Kotschneff. He used the technique of London (1927), which enables blood to be drawn from the deep blood vessels in unanaesthetized animals. Analysis of blood samples from the portal and hepatic veins of dogs before and after protein meals by modern biochemical methods would be worth while.

There is an important difference between the routes followed by amino-acids absorbed in the ordinary way and by intravenously injected amino-acids or hydrolysates. Normally, of course, all the amino-acids pass via the portal vein to the liver; and, as we have seen, the great bulk of them are apparently changed into polypeptides and proteins. Small amounts of amino-acids are, however, found in the general circulation, but evidently not in such high concentrations as after injections of amino-acids or protein digests. The injected hydrolysates go in the venous blood to the right heart, the lungs, the left heart, and thence in the arterial blood all over the body. If, according to the older theory, the amino-acids were straightway used by the tissues of the body, leakage by the kidney would probably not be as great as it is, but if they must first be changed into blood proteins by the liver, according to Whipple's view, then the dispersal of the material through the circulation would make the necessary transformation in the liver and removal of amino-acids from the blood a very gradual process. The kidney threshold for the separate amino-acids may thus be exceeded. This, it seems to me, is the main reason for the losses of N by the kidney after intravenous infusions. There are clearly many gaps in our knowledge, and it is important that steps should be taken to fill them.

Clinical Experiences

Notwithstanding our lack of knowledge, there is no doubt that protein hydrolysates have provided much success, even where their use has been very limited, as in this country. Very few cases have, however, been published. Two interesting ones came under my observation (Magee, 1946). Both were cases of homologous serum jaundice and were in *extremis* before treatment began; the response and recovery were spectacular. They were given 5% acid hydrolysate in amounts up to 1,000 ml. in twenty-four hours (50 g. of protein and 200 calories) at the rate of 500 ml. in about three hours. The hydrolysates were usually preceded and sometimes followed by 500 ml. of 5% glucose given in amounts up to 1,600 ml. (320 calories) in 24 hours. The rate of administration in North America varies from 350 to 600 ml. an hour of a 5% solution each of digest and glucose, and about 4 litres is apparently the maximum that can be given with impunity in twenty-four hours (200 g. of protein and 1,600 calories). Experience there indicates that it would be difficult to exceed this amount because of the care and attention required for the infusions and because of the risk of reactions and extensive thrombosis.

The conditions in which protein hydrolysates have been used with success include hepatitis, injury or disease of the bowel, intestinal obstruction, severe typhoid state, enteritis, colitis, severe burns, cyclic vomiting, peptic ulcers, and after operations. The most striking case I know of was reported by Brunschwig *et al.* (1945). The patient was kept alive for eight weeks entirely by venous infusions of protein hydrolysate plus glucose, and during this time

he had two severe operations—one for removal of a tumour and the other a bowel resection. Brunschwig, when I saw him in October, 1946, informed me that the man was enjoying a normal life about two years after his discharge from hospital.

Thrombosis

Thrombosis has occurred in every case treated with acid preparations that I know of in this country, but it would seem that it is less likely to occur with enzymic preparations. Although they have rarely reported thrombosis in their papers I found that the Americans have also been bothered with it. Brunschwig told me that in his famous case so many superficial veins were affected that he had difficulty in giving injections towards the end of the treatment. The Americans are now combating this complication with fair success by using different veins and giving no more than 500 ml. at a time by the same vein. Joliffe showed me in a New York hospital a novel method of infusion in an emaciated patient—through a cannula tied into a vein. He treated this patient with blood, then protein hydrolysate for a week, and later with a 25% solution of albumin. The improvement in the patient was remarkable. She had had a large intestinal resection and was in desperate plight before the treatment was started.

Energy Requirements

The energy requirement of an adult male confined to bed is probably not much less than 2,000 calories daily, and may be 2,400 or more in febrile states. If the maximum we can give by vein is substantially less than this, then we run the risk of the hydrolysates being used largely for energy purposes, so that nothing would be left over for reconstruction of damaged tissues. It is to avoid this that glucose is given immediately before or in solution with hydrolysates. To what extent this succeeds is unknown, but the question would not arise if we were able completely to satisfy the energy needs from non-protein sources and have, say, 70 g. of protein for reconstruction. This cannot be done with any combination of hydrolysates and glucose because stronger solutions are excluded owing to the risk of extensive thrombosis and losses via the kidneys, and with solutions of the present strengths the bulk of fluid which would have to be given would be too great.

Fats

As we have seen, the maximum energy we can hope to give by vein day after day is only 1,600—i.e., 400–800 calories less than requirements. There can be little doubt therefore, that a large proportion, maybe all in many cases of the injected hydrolysate is oxidized for energy, thus frustrating its primary purpose—namely, tissue reconstruction. Now that we have succeeded in making digests of proved value on a commercial scale, the problem remaining to be solved is how to "protect" the protein hydrolysates by sufficient non-protein energy-giving materials so that the bulk of the amino-acids and peptides will be spared for tissue-building. To do this we would require to give 2,000 calories or more a day in non-protein form.

At present we have no means of giving fats and are therefore restricted to glucose, but the maximum energy we can provide in this form is only about 800 calories a day. The energy problem then becomes one of incorporating fat in usable form in the injections. If this were possible we could reduce the protein hydrolysate about 75 g. more or less—i.e., to 1,500 ml. of solution. It would, however, be better to increase to 2,000 ml. and reduce the concentration of 3.5%, thereby lessening the risk of leakage by the

With glucose in a concentration of 5% this would give 400 non-protein calories, leaving 1,600 to come from fat in order to reach the 2,000 target. About 170 g. of fat would be required.

So far it has not been found possible to give to human subjects fats in amounts that matter, but research is proceeding. Hegsted, Hay, and Stare (1945) have got so far as to risk giving small amounts to patients, but reactions, none serious, have followed in several instances. Dunham and Brunschwig (1944) have also busied themselves on the subject, experimenting with dogs, but apparently with little success. The main difficulty seems to be to get an emulsion stable enough to stand sterilization. Ivy has been working vigorously on the subject, and he informed me at the International Physiological Congress in Oxford in July, 1947, that he had succeeded in making a stable emulsion with which he has kept dogs in N balance, constant weight, and good health by exclusively venous feeding for 42 days. Since then he has been good enough to send me the following particulars of his emulsion.

Preparation of the Emulsion

1. 50 g. of butter oil refined.
2. 2 g. of lecithin "purified."
3. 2.5 g. of "span 20" (a wetting agent).

Mix thoroughly and heat and mix on a steam bath. Then add, stirring, to :

4. 445 ml. of either 5% or 10% glucose solution made in triple-distilled water and containing 0.1% sodium cholate.

Homogenize five times at a pressure of 3,000-4,000 lb. per square in. (210-280 kg. per cm.²) in a Cherry-Burrell viscolizer (junior model) or its equivalent. Autoclave twice at 10 lb. for 10 minutes within 24 hours.

This yields a mixture of : 10% fat by weight, 0.4% lecithin, 0.5% span 20, 0.1% sodium cholate, 5% glucose.

1. The butter oil is refined by melting and removing curd and water. Then the oil is washed with three or four volumes of hot freshly distilled water three times. Highly refined oil may also be used, though most experiments have been done with butter oil.

2. The "purified lecithin" is a soya-bean lecithin prepared by the "Lecithin" Products Co., Elmhurst, New Jersey. If the lecithin is not purified, or even if a 1% concentration of this lecithin is used, anaemia results.

3. Span 20 is a sorbitan wetting agent made by the Atlas Powder Company, Wilmington, Delaware. It is the best (non-toxic) of numerous wetting agents so far used.

4. Sodium cholate is obtained from Breon and Co., of Kansas City, Missouri, or G. D. Searle and Co., of Chicago.

The emulsion is infused slowly intravenously so that the total calorie and nitrogen requirement is given in six to eight hours. Various protein hydrolysates have been used (one by Mead Johnson and Co., Evansville, Indiana, and another prepared by Cutter Laboratories, Berkeley, California). Enough of the hydrolysate is given to keep the dogs in N balance. It can be used separately or mixed with the emulsion.

The total daily mineral and vitamin requirement may be added to the solution. Calcium and iron may disturb the emulsion; these should be given separately.

There can be no doubt that if we succeed in making a preparation suitable for human intravenous use and containing about 75 g. of protein hydrolysate and 2,000 non-protein calories in 2 litres or so we shall have a therapeutic agent of great possibilities. This work of Ivy and his colleagues is an important step in that direction.

Summary

Until recent years we had no adequate means of combating the malnutrition which complicates many diseases, especially

those directly hindering the ingestion, digestion, absorption, or metabolism of food. A preparation of protein suitable for intravenous use and metabolizable by the body was required. Although there is evidence suggesting that the plasma proteins can supply the elements for tissue growth and repair, it is doubtful if transfusion with human plasma is the solution of the problem; sufficient human blood might not be obtainable for such extensive use.

Enzymic hydrolysates of protein suitable for administration by vein have been prepared in U.S.A. and Great Britain and have been used with impunity and success in a wide variety of conditions in which secondary malnutrition is a prominent feature. They include acute hepatitis, comatose states, typhoid state, infantile diarrhoea, and post-operative conditions. The hydrolysates are usually given in 5% solution with 5% glucose at about 500 ml. an hour to a maximum of about 4 litres (200 g. of protein and 1,600 calories) in twenty-four hours. Thrombosis can be lessened by using different veins and giving no more than 500 ml. at a time by the same one.

A defect in the present procedure is that a large proportion of the injected hydrolysate is oxidized to supply energy and is thus diverted from its intended purpose of tissue-building, because it is not yet possible to incorporate enough non-protein calories in the infusion fluid.

It is desirable to administer up to 2,000 calories as glucose and fat emulsion; the hydrolysate could then be reduced to about 2,000 ml. of a 3.5% solution (70 g. of protein) and the bulk would probably be used for tissue repair.

It has not yet been possible to make a fat emulsion suitable for human use; but dogs have been kept in N equilibrium for six weeks by intravenous feeding on protein hydrolysates and glucose-fat emulsions which withstand sterilization.

An important problem remaining to be solved is to check the urinary leakage of hydrolysate which occurs in the first thirty minutes or so after starting infusions.

I am indebted to Prof. Himsworth and Dr. Stannus for comments on the paper, and especially to Prof. Ivy for his great courtesy in allowing me to publish for the first time the details of his fat emulsion.

The number of technical dictionaries available to the medical worker interested in foreign languages is very limited, and any reliable addition to their number is welcome. The *English-Spanish Chemical and Medical Dictionary*, by Morris Goldberg (pp. 692, 50s., McGraw-Hill, New York, 1947), will be of more use to Spanish-speaking medical men than to their English-speaking colleagues and should provide them with a fairly complete guide to British and American technical terms. The dictionary is up to date and includes such newcomers to medicine as streptomycin and thiouracil. Definitions of words are given in Spanish. It is inevitable that in a new book there should be a number of relatively important omissions. For example, the author has omitted the names of some muscles while including others less commonly referred to. Nevertheless, he has prepared the dictionary as a whole with care, and we can recommend it not only to those interested in medicine and the allied sciences but also to chemists and biologists.

RARER MANIFESTATIONS OF HERPES ZOSTER

A REPORT ON THREE CASES

BY

THOMAS PARKINSON, M.D., M.R.C.P.

Medical Tutor, St. Bartholomew's Hospital

Herpes zoster usually presents as a mild illness with a characteristic rash accompanied by local pain and preceded by a varying degree of constitutional disturbance. Post-herpetic neuralgia is a common sequel, but complications are rare. Of the complications which have been recorded a concomitant varicelliform eruption is perhaps the most common. The rarer, and more serious, complications include lesions of the motor neurones, myelitis and meningitis, encephalitis, and osteoarthritis (Wilson, 1940). It is the occurrence of such complications that at once dispels the concept of zoster as a uniformly benign infection confined to the sensory neurones. Moreover, these complications open controversial aspects on the aetiology and pathology of the disease and upon the difficult problem of the relationship between zoster and varicella. The following three cases are placed on record as exemplifying certain of these rare complications. All three patients showed evidence of affection of motor neurones, and two of them exhibited a generalized eruption during the course of the disease.

Case 1

Zoster, accompanied by paralysis, in the distribution of the fifth cervical segment.

A solicitor's clerk aged 60 was admitted to hospital on July 4, 1947. He gave a history of chicken-pox in childhood. In 1918 he had sustained a shrapnel wound of the right elbow, which had left him with a complete ulnar lesion on that side and much limitation of movement of the elbow-joint.

Six weeks before his admission he had suffered from acute pain in the right shoulder. Three days later a rash appeared in the antecubital fossa and rapidly spread up the outer side of the arm as far as the right shoulder. Three days after the appearance of the rash he noticed, quite suddenly, that his right arm was weak and that he could raise the arm from the side only with difficulty. The weakness increased over the next few days until the right arm was quite useless. Since that time the rash had cleared up, but the weakness had not improved at all. After the disappearance of the rash he had felt tingling and numbness in the area of skin previously affected.

Examination showed a healthy well-built man. There was a pigmented scarring over the site of the recent rash, distributed on the outer side of the upper arm from the shoulder to the elbow—i.e., in the cutaneous distribution of the fifth cervical dermatome. There was some hypo-aesthesia to pin-prick and cotton-wool sensation in the same area. There was considerable wasting of the right deltoid, supraspinatus, and infraspinatus muscles. No abduction of the shoulder was possible, although a flicker of muscular contraction was palpable over the deltoid muscle when abduction was attempted. Slight contraction of the supraspinatus and infraspinatus was likewise palpable over the muscle bellies. The biceps and brachioradialis muscles on the right side were weaker than those on the left. Under the nomenclature suggested by the Medical Research Council (1942) the muscular contractions at this time were: deltoid 1, supraspinatus 1, infraspinatus 1, biceps 4, brachioradialis 4. There was a deep scar of the old wound on the inner side of the right elbow, and below the elbow there was a complete ulnar-nerve palsy. The biceps and supinator reflexes on the right side were impaired; the triceps-jerk was normal. The remainder of the physical examination revealed nothing abnormal. Lumbar puncture on July 6 showed a clear fluid under normal pressure. The cerebrospinal fluid contained 5 cells per c.mm. The protein was 0.055%, with a slight increase

of globulin, and the chlorides 0.75%. The Wassermann reaction and Lange curve were negative.

The patient was treated by resting the arm in an abduction splint and by faradic stimulation of the muscles affected. He was discharged from hospital on July 30 to continue treatment as an out-patient, and at this time there was pronounced objective improvement. He was last seen on Aug. 16, when recovery was almost complete.

Case 2

Ophthalmic zoster with generalized eruption, followed by weakness of the levator palpebrae.

A housewife aged 48 was admitted to hospital on July 9, 1946. There was no history of previous illness, and she denied having had chicken-pox. She complained of an irritation on the left side of the forehead for the previous week, and on July 6 she had first had severe neuralgic pains over the left eyebrow. On the day before admission the left eye became swollen and painful, and a rash was noticed on the forehead. On admission the patient looked ill and had a fever of 101.8° F. (38.8° C.). There were a moderate number of vesicles on erythematous bases in the distribution of the ophthalmic division of the trigeminal nerve on the left side. The left eye showed conjunctival injection, with some photophobia and extreme tenderness to pressure. There were no other abnormal signs, and the rest of the skin was clear. During the next three days (July 10 to 12) the number of vesicles increased, the erythema spread, and the upper and lower lids became grossly oedematous. The appearance was now quite typical of a severe herpes zoster.

On July 13 the patient complained of irritation of the skin. Examination then showed that she had a generalized eruption on the trunk and proximal parts of the limbs, with a single lesion on the face. The eruption was quite typical of that seen in varicella, and the subsequent course of pustule formation and healing followed as customary in that disease. It was noted, however, that after the first 24 hours no fresh crops of vesicles arose. Whether or not the previous lesions had occurred in crops is not known, as no examination of the skin had been carried out between the initial examination and the complaint of irritation. As the herpes recovered it was evident that there was considerable weakness of the levator palpebrae muscle on the left, giving rise to obvious ptosis. The scabs from the varicelliform rash separated on Aug. 1, 14 days after their occurrence, and the patient was allowed to leave hospital. The ptosis was still present on discharge and persisted for many weeks. The patient was last seen in December, 1946, when the ptosis had completely recovered. At no time was there any oculomotor paralysis or abnormality in the pupil response.

Case 3

Zoster of trigeminal and cervical distribution accompanied by generalized eruption and followed by facial palsy.

An engineer aged 43 was admitted to hospital on July 13, 1947. In his youth he had suffered from scarlet fever, diphtheria, and chicken-pox. In February, 1945, he developed shingles over the lower half of the left side of the face, the upper part of the neck, and behind the left ear. He stated that in spite of careful search no lesions were found in the ear or inside the mouth. Four days after the appearance of the zoster he developed "an attack of chicken-pox," and because of this he was transferred to an isolation hospital. Within a day or two he suddenly developed a complete left facial palsy, which persisted until his discharge from hospital some five weeks later. Since that time there had been some improvement in the weakness of the face, but he had always been greatly troubled by difficulty in eating, numbness of the face, and severe neuralgia. His present admission followed a cerebral vascular accident which had occurred twelve weeks previously and which had caused aphasia and weakness of the right arm and face. The disability arising from this cerebral lesion had almost disappeared on admission.

Examination showed a pronounced left lower neurone facial weakness, together with diminished sensations over the lower

part of the face and on the inside of the left cheek. The tongue was protruded centrally. Although the patient complained of lack of appreciation of taste on the left side of the tongue, the presence of hemiageusia was not confirmed by crude tests. In addition to these signs there was an increase in the tendon reflexes and a diminution of the abdominal reflexes on the right, representing the residuum of the recent cerebral thrombosis. His blood pressure was 210/120. No other abnormal findings were present. Lumbar puncture showed a clear fluid under normal pressure. The cerebrospinal fluid contained 3 cells per c.mm.; the protein was 0.04%; and the Wassermann reaction and Lange curve were negative.

Discussion

Zoster Generalisatus and Its Relation to Varicella

The occurrence of a varicelliform rash in the course of herpes zoster is a well-recognized entity. It is variously referred to as zoster generalisatus, zoster universalis, and varicelliform zoster. The condition was probably first described by Tenneson in 1893, and many examples have been recorded since. Minet and Leclercq (1911) collected 25 cases, and Parkes Weber (1913, 1916a, 1916b) described several cases and quoted 20 references. Most reports stress its occurrence in elderly patients. The extent of the eruption varies from the presence of a few aberrant vesicles to a diffuse eruption indistinguishable from the exanthem of varicella. The rash in Case 2, described above, was typical of varicella. Case 3 was not seen in the acute phase of the disease, but the eruption was evidently so like that of varicella that the patient was transferred to an isolation hospital.

The condition is of particular interest in that it provides a no-man's-land in the perennial battle between the monists and the dualists over the relationship between zoster and varicella. It has been assumed by some writers that the eruption constitutes a true attack of chicken-pox (Allen, 1944; Manning, 1944; Sharpe, 1946; and others), or that the concurrence of the two conditions is proof that zoster and varicella are but phases of one and the same disease (Le Feuvre, 1917). But, as Parkes Weber (1916a) has pointed out, this conclusion is hardly justified, as some of the cases show only a few aberrant vesicles, and evidence of an increase in cases of zoster during epidemics of varicella is lacking.

The experimental work of Kundratitz (1925) and Bruusgaard (1932) has an important bearing on this issue. These writers showed that the inoculation of children with vesicle fluid from cases of zoster produced a quasi-varicella rash and that contacts with these children also developed an eruption indistinguishable from varicella. Bruusgaard draws no definite conclusions from this work, but points out that the findings are compatible with the postulate of Haslund (1900) that the difference in the manifestations of infection with the zoster virus might well depend on the portal of entry. Haslund suggested that in zoster the virus gains access to the body via the nasopharynx and spreads to the nervous system, and that the generalized eruption is due to haematogenous dissemination to the skin.

The problem of the relationship between the two diseases is clearly not proved (cp. Wilson, 1940) and will remain so until further facts accumulate. Such data will become available only as the result of systematic investigations, and two lines of approach seem possible. The first is an extension of the work of Aitken and Brain (1933) on the complement-fixation test for the zoster virus, which they found to be positive in all of nine cases of zoster. Application of this test to cases of varicella does not seem to have been undertaken. The second line of approach, suggested by Le Feuvre (1917) and Taylor (1945), is the compulsory notification of herpes zoster, so that its

epidemiology might be compared with that of varicella. From observations made in a relatively isolated community Pickles (1939) showed that the epidemic peaks of the two diseases roughly correspond.

Motor Symptoms in Zoster

Of considerable interest and importance are the rare cases of zoster in the course of which the motor nervous system is affected. Involvement of the upper motor neurones has been described (Parkes Weber, 1915), and references to this condition are given by Carter and Dunlop (1941). The majority of recorded cases, however, refer to lesions of the lower motor neurones. These lower motor neurone pareses may be conveniently divided into three clinical types: facial palsy, oculomotor paresis, and segmental spinal-cord paralysis. The three cases described above provide one example of each of these types. As will be seen in the discussion that follows, the mechanism of the production of the motor symptoms is probably different in the three types. In facial palsy the motor fibres are incidentally involved in their transit through the geniculate ganglion, oculomotor lesions arise from peripheral spread of the infection, and spinal paralyses are probably due to actual involvement of the spinal cord by the zoster virus.

Facial palsy is by far the commonest of the motor lesions (Hunt, 1909). It was first clearly described by Ramsay Hunt (1907), and the syndrome often goes by his name. The primary lesion is in the geniculate ganglion, and the herpetic eruption occurs in the cone-shaped area of the cutaneous distribution of the facial nerve, which includes the posterior portion of the tympanic membrane and the external canal, the concha, the antitragus, and the antihelix. In addition to this classical syndrome, facial palsy occurs as a complication of trigeminal herpes (Wilson, 1940; Spillane, 1941). In such cases presumably the Gasserian and geniculate ganglia are affected simultaneously.

An important group of cases is that in which trigeminal herpes occurs with facial palsy but without herpetic eruption in the seventh-nerve distribution. In these cases, of which Case 3 is an example, it has been suggested that the inflammation of the geniculate ganglion is extensive enough to produce paresis, but not to produce herpes (Sharpe, 1915). The significance of these cases is that they provide examples of "zoster sine herpete" of the geniculate ganglion, with abundant evidence of zoster of the neighbouring ganglia. It is but a short step to the assumption that certain cases of "idiopathic" Bell's palsy might be formes frustes of zoster. Ample substantiation of this supposition is to be found in the work of Aitken and Brain (1933), who demonstrated a positive complement-fixation reaction for zoster in four out of 22 cases of facial palsy in which there was no rash. Spillane (1941) brought other evidence to bear in support of this concept when he described a small epidemic of zoster in the course of which a single case of Bell's palsy was seen.

When oculomotor palsy occurs in the course of zoster it does so invariably as a complication of zoster ophthalmicus. The condition was probably first described by Vernon in 1868, and cases were later reported by Hall (1903), Mules (1903), and Parkes Weber (1916a, 1916b). The paresis may be slight, as in Case 2, in which ptosis was the sole manifestation, or more severe, producing complete paresis of the muscles supplied by the third, fourth, or sixth nerves (Hunt, 1909; Carmody, 1937). The clinical aspect is fully reviewed by Edgerton (1942). According to Kinnier Wilson (1940) the probable mechanism of its production is that spread takes place via the small communicating fibres between the first division of the

trigeminal nerve and the oculomotor nerves in the wall of the cavernous sinus. From analogy with geniculate zoster it is tempting to assume that certain of the oculomotor paralyses, especially when associated with ophthalmic neuralgia, might be due to "zoster sine herpette." No work seems to have been done on the complement-fixation test in such cases. It is of interest to note that this possibility was suggested by Mules (1903) some years before the classical work on geniculate zoster by Ramsay Hunt (1907).

Segmental paralysis of spinal-root distribution is rare in the course of zoster, but the complication was clearly described by Sir William Broadbent (1866), who reported a case in which paralysis of the arm followed herpes of the arm and neck. Joffroy (1882) described two cases—one affecting the deltoid and the other the small muscles of the hand. Most of the reports of cases describe cervical segment paralysis (Buzzard, 1902; Wilson, 1940), but involvement of the abdominal muscles (Taylor, 1895) and of the leg muscles (Carter and Dunlop, 1941) has been recorded. In Case 1, reported above, the cutaneous rash and the paralysis were in the distribution of the fifth cervical segment. Recovery was practically complete in three months from the onset. That the prognosis is not always so good is indicated by Carter and Dunlop (1941), in neither of whose cases had complete recovery taken place in nine months to one year.

These cases of segmental motor paralysis throw further light on the pathology of herpes zoster. The primary lesion in zoster is usually to be found in the posterior root ganglion. Head and Campbell (1900), in a study of the post-mortem changes, demonstrated that these ganglia showed round-cell infiltration, haemorrhage, and cell necrosis. They concluded that the changes in the posterior roots and horns and in the peripheral nerves were secondary and degenerative. This is undoubtedly the common state of affairs, but it fails to explain the rare cases in which there is definite clinical evidence of motor-root lesions. Further light is thrown on this problem by the work of Lhermitte and Nicolas (1924). These authors examined the spinal cord of a patient who died of an incidental disease seven weeks after an acute attack of zoster. In this case there was, in addition to the perivascular infiltration and demyelination in the posterior horns, marked evidence of inflammatory changes in the anterior horns. In spite of this there had been no clinical mention of a motor lesion. This finding confirms affection of the anterior and posterior horns of the spinal cord, and the presence of cord inflammation is borne out by the lymphocytosis and the increase in the protein content of the cerebrospinal fluid which commonly occurs (Wilson, 1940; Carter and Dunlop, 1941). The pleocytosis of the cerebrospinal fluid, the clinical manifestations of motor segmental paralyses, and the anterior horn changes in these cases bear a striking resemblance to those found in poliomyelitis. Parkes Weber (1916a) has taken this analogy even further by suggesting that the two diseases may in fact be caused by the same virus. As evidence he quoted the occasional appearance of the diffuse herpes in certain cases of poliomyelitis and the concurrence of epidemics of the two diseases. Further, he suggested that certain cases of painful muscle paresis of obscure aetiology might be regarded as cases of "zoster sine herpette."

Conclusions

In causing infection of the human body the herpes zoster virus shows a predilection for nervous tissue and the skin. In the classical form the brunt of the infection is borne by the sensory ganglia, the resulting symptoms being pain

and a cutaneous eruption in the peripheral distribution of the fibres proceeding from the affected ganglia. Study of the rarer manifestations of the disease shows that the infection often spreads beyond these confines. In some cases in which motor symptoms occur there is clinical and pathological evidence that the anterior horn cells of the spinal cord are affected in a manner similar to that in poliomyelitis. In others the infection produces an exanthem clinically identical with that of varicella.

From the available evidence it seems no more reasonable to deduce that varicella and zoster are caused by the same virus than it would be to make a similar deduction regarding zoster and poliomyelitis. It seems much more probable that the virus is capable of producing a range of clinical manifestations varying from simple motor lesions on the one hand to generalized skin lesions on the other, and that the classical form of the disease lies midway between these extremes. This clinical range might be represented as follows: poliomyelitis-like illness—zoster sine herpette—herpes zoster with paralysis—classical herpes zoster—herpes zoster with generalized eruption—varicelliform zoster (sine herpette). This suggestion is of course speculative, and it takes no account of the encephalitic symptoms which are said to occur. Nevertheless, clinically proved examples of each group are to be found in the literature, with the exception of the hypothetical poliomyelitis-like illness, and it is unlikely that evidence of this will be found in the absence of specific complement-fixation tests on such cases.

Summary

Three cases of herpes zoster showing unusual motor and cutaneous manifestations are described. It is suggested that the zoster virus produces a pleomorphic group of diseases with varying degrees of cutaneous and nervous symptoms. Further evidence on certain aspects of the disease could be obtained by immunological and epidemiological investigations.

I wish to thank Dr. E. R. Cullinan for permission to publish Case 3, Dr. A. W. Spence for permission to publish Case 1, and Dr. Paul Abbey for his assistance in Case 2.

TREATMENT OF CHRONIC ULCERATION AFTER IRRADIATION OF PLANTAR WART

BY

MORTIMER H. SHAW, M.B., B.Sc., F.R.C.S.
(From the Plastic Surgery Unit, St. James's Hospital, Leeds)

The plantar wart is commonly cured by irradiation. In wartime the condition was a frequent cause of minor disability in the Services, and was treated by radiotherapy under out-patient arrangements. A record of dosage sometimes failed to follow the patient on his travels; and over-exposure undoubtedly occurred in some instances. Chronic intractable ulceration of the sole resulted in prolonged disability out of all proportion to the importance of the original lesion.

The ulcer heals slowly or not at all when treated with recumbency and local applications. Deep fibrosis leads to an unstable tender scar on the sole which prevents normal walking. Recurrence follows simple excision performed without skin replacement. A "free" skin-graft is unlikely to provide a permanent cover in this situation even if it succeeds on the relatively avascular base. Local pedicled flaps are as unsatisfactory on the sole as they are on the palm.

Radical excision down to healthy tissue and outwards to normal skin, however, leaves a defect which can readily be filled by means of a direct pedicled flap from the opposite leg. This provides a stable skin cover with a subcutaneous pad. The patient can walk in normal shoes without pain in six to eight weeks. It should be emphasized that this method of treatment is advised for ulceration which results in all probability from the radiation itself, and not for that which may follow repeated attempts to eradicate the plantar wart by mechanical, thermal, and chemical means.

Case 1

A married woman aged 36 complained of an extremely tender ulcer on the sole of the foot. The ulcer had persisted for two and a half years after a repeated application of deep x-ray therapy to a plantar wart. Excision had been performed more than once, and many remedies had been applied locally. The ulcer varied in size and in degree of infection, but had never healed.

When seen on Sept. 4, 1944, the ulcer was 1 1/2 in. (1.25 cm.) in diameter, had an indolent rolled edge, but was relatively free from infection after treatment with penicillin cream during a recent puerperium. A haemolytic staphylococcus was cultured.

On Sept. 7 the ulcer was excised down to healthy plantar fascia and a margin of apparently healthy skin was included; a pedicled flap was raised from the opposite leg to fill the defect. A five-day systemic course of penicillin was given. The pedicle was separated and the flap implanted on Sept. 26. Healing was rapid. The patient left hospital able to walk in normal shoes on Nov. 3.

The pathologist's report was as follows: "The skin changes are compatible with irradiation dermatitis (hyperkeratosis, obliterative endarteritis, and atrophic changes in accessory skin structures), followed by superficial ulceration and subcutaneous fibrosis. There is no evidence of malignant change in the section examined."

Case 2

A soldier aged 34 had suffered from the effects of a plantar wart since 1943. This had been pared by a chiropodist, excised at least four times in different hospitals, and cauterized. The ulcer had been treated with permanganate, salicylic acid, vitriol, formalin, flavine, eusol, gentian violet, penicillin cream, and several other less certain substances. Deep x-ray treatment had been given at more than one hospital, and in several doses.

FIG. 1.—The ulcer in Case 2.

When seen on July 12, 1946, there was an ulcer on the sole of the right foot, 1 1/2 in. (3 cm.) in diameter (Fig. 1). The base consisted of firm tender granulations with a yellow slough. The edge was indolent and blue in colour, and was surrounded by an area of dusky induration. The Wassermann reaction was negative.

The ulcer was excised on July 29 and the defect, which extended down to plantar fascia and measured 2 in. (5 cm.) square, was filled by means of a direct pedicled flap from the

FIG. 2.—Application of a pedicled flap from the opposite leg.

opposite leg (Fig. 2). The secondary defect of the donor leg was closed by a dermatome graft from the thigh. A systemic course of penicillin was administered for five days.

The pedicle was divided on Aug. 23, and the flap implanted. The patient began to walk after a course of physiotherapy. He went before the medical board on Oct. 24 and was discharged

FIG. 3.—Showing the foot soundly healed.

from the Army. The foot was soundly healed (Fig. 3). The pathologist's report was: "Portion of skin shows ulceration with fibrinoid necrosis in the floor of the ulcer."

EXERTION HAEMOGLOBINURIA

REPORT OF A CASE

BY

E. J. L. LOWBURY, M.A., B.M., B.Ch.,
Late Major, R.A.M.C.

AND

A. P. L. BLAKELY, M.D.
Late Lieutenant-Colonel, R.A.M.C.

The form of paroxysmal haemoglobinuria associated with exertion is rare and its pathology is imperfectly understood. The clinical features and the results of laboratory investigations undertaken in a case studied by us are here recorded.

Case History

The patient, a European sergeant aged 33, first came under our observation at the end of July, 1944, when he was seen as an out-patient by one of us. He brought with him a sample of almost black urine which he had passed after playing a game of football. He gave the following interesting history.

In civil life he had worked as a stevedore and had never noticed any urinary abnormality or suffered from any illness. In September, 1940, on returning to the U.K. from France, he noticed that after a cross-country run his urine was dark. The same occurrence was noticed on two subsequent occasions under similar circumstances. He then remained free from symptoms until June, 1942, when again after a run his urine was dark. He was admitted to hospital for investigation, the results of which are not known to us, but his medical category was lowered to B. In June, 1943, his category was raised to A again, as he was eager for service afloat. In June, 1944, he arrived in East Africa, and early in July, after a route march, he had his first recurrence of the old symptom. On July 27 he played football, and it was a sample of the urine passed after this game that he brought with him to hospital. Examination of this specimen of urine showed: colour very dark brown; reaction acid; albumin + + + +; benzidine test + +; deposit: a few red blood cells, granular casts +, urates ++, a few calcium oxalate crystals.

He was admitted to hospital on July 31 for further investigation. It was established that a 20-minutes run invariably resulted in a paroxysm of haemoglobinuria lasting several hours. No constitutional disturbance accompanied the paroxysms, but there was some aching in the back and abdomen. The patient was of good physique; no other signs of disease were detected, and before an attack the urine contained nothing abnormal. It was decided to lower his medical category to C for six months, and he was discharged to duty in this category on Aug. 30.

During the next three months the patient reported that the paroxysms were becoming more frequent and that less exertion was required to produce them. Actions such as hauling on ropes were now apt to be followed by an attack, and the condition was becoming a liability in his daily work. He was readmitted to hospital on Nov. 29, and the investigations detailed in Table I were carried out.

An attempt was made to demonstrate the presence of intra-vascular haemolysis. The patient's red blood corpuscles and serum were mixed and incubated at 37° C. for two hours, with and without previous exposure to a temperature of 4° C. for 30 minutes, and with and without added complement (Donath-

Landsteiner reaction). Foreign group O cells and patient's serum, and patient's cells and foreign serum, were also set up against each other in a similar manner. All these tests were carried out on blood taken from the patient 3 minutes, 15 minutes, and 30 minutes after the beginning of a 30-minute

TABLE I.—Results of Tests Before and Immediately After a 30-minute Run

Test	Before Exercise	After Exercise
Haemoglobin (Sahli)	120%	106%
Red cells	5,750,000/c.mm.	5,320,000/c.mm.
White cells	9,000/c.mm.	8,400/c.mm.
Neutrophils	74%	78%
Lymphocytes	19%	18%
Monocytes	5%	3%
Eosinophils	2%	0.5%
Basophils	—	0.5%
Primitive white and red cells ..	Nil	Nil
Platelets	545,000/c.mm.	475,000/c.mm.
Coagulation time (at 30° C.) ..	5 minutes	6 minutes
Bleeding time	60 seconds	60 seconds
Reticulocytes	0.6%	0.4%
Blood group	O	O
Fragility of red cells	Total lysis in 0.34% NaCl; no lysis in 0.42% NaCl (within normal limits)	Total lysis in 0.34% NaCl; no lysis in 0.42% NaCl (within normal limits)
Packed cell volume	41%	40%
Mean corpuscular diameter	6.8μ	6.8μ
" " volume	71 c.μ	75 c.μ
" " average thickness	1.9μ	2.1μ
Van den Bergh reaction	Direct, nil.	Marked haemolysis
Icterus index	Indirect, 1.6 units	
	6.6	

run, and then 45 minutes, 90 minutes, and 7 hours after the exercise was finished. Haemolysis *in vitro* was not demonstrated in any of these tests, or in tests for haemolysis on small amounts of fluid aspirated from muscle during and after exercise. Examination of urine taken at intervals after the beginning of exercise gave the results shown in Table II.

A rising and falling curve of oxyhaemoglobinaemia, which approximately paralleled the curve of haemoglobinuria, was demonstrated by tests on blood taken at intervals during and after exertion. It was possible to make only a rough estimate

TABLE III

Time Since Exercise Began:	During Exercise			After Exercise		
	3 min.	15 min.	30 min.	75 min.	120 min.	450 min.
% Hb (Sahli) ..	Less than 0.2	0.5	1.5	1	0.2	Less than 0.2
Hb (calculated from Sahli)	Less than 34 mg.	85 mg.	255 mg.	170 mg.	34 mg.	Less than 34 mg.

of haemoglobin by Sahli's method; the figures obtained are shown in Table III. The absorption spectrum for pseudo-methaemoglobin was not found in any of the sera examined.

The following experiment was performed in an attempt to determine if haemolysis occurs locally in muscle during exercise. First, 5 ml. of blood was withdrawn from a vein in the right arm and allowed to clot. A sphygmomanometer cuff was then applied to the left upper arm and inflated to a pressure of 100 mm. Hg. The patient then exercised the left arm, alternately extending and flexing the wrist and fingers for two minutes. At the end of this time blood was withdrawn from a vein in the left arm, with the sphygmomanometer cuff inflated. The serum from these two specimens showed no perceptible difference in colour. The experiment was repeated, this time releasing the cuff just before blood was withdrawn; the specimen presumably contained blood from all parts of the occluded limb, and it, too, showed no trace of haemolysis.

TABLE II.—Results of Urine Examinations

Hours after Exercise Started	Appearance	Spectroscopy	Protein	Sugar	Deposit
1/2	Dark brown, turbid	Oxyhaemoglobin + +; methaemoglobin + + +	+++	Nil	Granular casts + + +; epithelial and pus cells +
1	Dark brown, very turbid	Methaemoglobin + + + +	+++	"	Granular casts and epithelial and pus cells +
1 1/2	Dark brown, turbid	Methaemoglobin + + +	++	"	Granular casts and epithelial cells +
2	Brown	Methaemoglobin + +	+	"	"
3	Pale brown, slightly turbid	Methaemoglobin +	Trace	"	Epithelial cells +
7	Amber, clear	No blood pigment	"	"	Pus cells and epithelial cells +
24	"	"	"	"	"

Finally it was decided to test the effect of posture. The patient stated that 20 minutes' vigorous swimming had not precipitated an attack. In our experiment he was instructed to "cyele" on his back, supporting his buttocks on his hands, his flexed elbows resting on the bed. This position overcorrected any possible lordosis. After 10 minutes' vigorous exercise in this position blood was withdrawn from a vein. The serum from this specimen showed no trace of haemolysis, and urine passed shortly afterwards was also clear of protein and of haemoglobin derivatives.

Discussion

Our experiments support the view that exertion haemoglobinuria results from haemolysis during exertion in the erect or extended position. This agrees with the common view. Cases, however, seem to vary in their degree of dependence on the postural factor. Thus in the case recorded by Makin (1944) haemoglobinuria was strictly postural, and did not occur after exercise on a bicycle, whereas in the case recorded by Witts (1936) running with bent back and work on the bicycle ergometer were followed by haemoglobinuria. The postural factor and the common association with lordosis suggest that the condition is allied to orthostatic albuminuria. Bicycle exercise in Makin's case was followed by albuminuria but not by haemoglobinuria. Orthostatic albuminuria was not present in our case.

The failure to demonstrate circulating haemolysin is of little significance and does not rule out the occurrence of intravascular haemolysis; for unless combination with red cells is prevented by special factors, as it is in the case of cold haemoglobinuria, haemolysin liberated into the circulation is likely to be fixed rapidly. In nocturnal haemoglobinuria all efforts to demonstrate circulating haemolysin have failed (Witts, 1936). The failure to demonstrate local haemolysin in muscle is in keeping with the postural features of the disorder and with the view of Witts, who regards the kidney as the source of the haemolysin. He considers intravascular haemolysis "hardly conceivable" in view of the absence of anaemia and the slightness of systemic changes and of haemoglobinaemia; he regards a local haemolysis in the vessels of the kidney as more probable.

According to Whitby and Britton (1944), in exertion haemoglobinuria "there are neither the constitutional symptoms nor the haemoglobinaemia so characteristic of haemoglobinuria from cold." In our case there was a cherry-red concentration of haemoglobin in the serum, and it would seem that the lowering of the blood haemoglobin level was slight because haemolysis was of short duration only, accompanying tiring exertion in the vertical posture. Whitby and Britton state that in cold haemoglobinuria haemoglobin appears in the urine when the free haemoglobin in the plasma exceeds 100 to 140 mg. per 100 ml. This is higher than the plasma haemoglobin level recorded after exercise in Witts's case (46.5 mg.) but considerably lower than that recorded in ours.

History of an injury is another inconstant feature in exertion haemoglobinuria, which, however, helps to incriminate an abnormal kidney as the immediate cause of haemolysin production. No history of injury was elicited in our case, but the disease had come on rather suddenly shortly after a campaign, when slight injuries might have been ignored. In contrast to the usual history, our case resembled that of Witts in showing symptoms for a period (with intermissions) of considerably more than one year. The age at onset of the complaint was much above the average, and it is of interest that the condition recurred with unusual severity when the patient came to the Tropics.

Summary

A case of paroxysmal haemoglobinuria of exertion is described.

Laboratory investigations, including attempts to demonstrate circulating haemolysin, are described and discussed.

Our thanks are due to Brig. R. Cormack, D.M.S., E.A. Command, for permission to submit this article for publication.

"TRIDIONE" IN THE TREATMENT OF PETIT MAL

BY

A. J. M. BUTTER, M.D.

Medical Officer, St. David's Hospital, London

Tridione, the synthetic anticonvulsant drug (3,5,5-trimethylloxazolidine-2,4-dione), has been extensively used in the treatment of the petit-mal epilepsies by investigators in America since 1944.

A Preliminary Investigation

Recently, when supplies became available in this country, a preliminary investigation was made at St. David's Hospital (for epilepsy), the findings of which are tabulated below. Most of the patients (who are sane males suffering from idiopathic epilepsy, and whose ages range from 17 to 56) have been taking the drug for three months.

Tridione is supplied in 0.3 g. capsules. So far it has been found that the apparently optimum dose in the average case is four capsules daily, in divided doses. One patient aged 17, however, has had his petit-mal attacks abolished by taking only two capsules daily. The drug was given in addition to other medication, such as phenobarbitone and "epanutin" (soluble phenytoin), which the patients had previously been taking.

Convulsive seizures of the grand-mal type did not appear to be reduced by tridione in any case, and one man experienced, possibly as a coincidence, an increase in the number of his fits. All the patients suffered from petit-mal except one whose seizures were of the myoclonic type. This man's condition did not improve. Another, however, who had myoclonic spasms as well as ordinary petit mal, states that he feels better than he has done for years.

It is possible that the patients who showed no improvement might have been benefited had they been given more than six capsules daily. Unfortunately a shortage of supplies precluded an increase of this dose.

No. of patients	23
Entirely free from petit mal	4 (17.4%)
Petit mal reduced by more than half ..	12 (52.2%)
Definite but slighter improvement ..	2 (8.7%)
No improvement, or toxic symptoms necessitating withdrawal of drug	5 (21.7%)

Because of the notorious difficulty in obtaining an accurate record of petit-mal attacks each patient was given a notebook, and in this he marked down every attack of which he was aware, or which any fellow patient or member of the nursing staff observed. For the purpose of comparison the patients had kept similar records of their attacks for a period of two months before starting tridione medication.

A few days after beginning to take the drug approximately four-fifths of the patients reported a reduction in the number of their petit-mal attacks. After a week or 10 days no fewer than 19 of the 23 patients mentioned that on walking out of a building into the open air they found the

light too bright. This phenomenon was variously described as "dazzle," or "glare," or "a whiteness like mist over everything." Some patients stated that they found reading in the open air to be impossible, and others said that objects appeared to have changed colour, as, for example, a familiar blue motor-car seemed to be cream-coloured. In most instances the sensation ceased after a short interval, but 10 of the men found it trying and were glad to wear dark glasses to mitigate the effect.

Five men were aware of slight drowsiness, apparently due to the drug; one complained of lack of concentration, and one of restlessness. Two developed slight ataxia; two complained of hiccup, and two of slight epigastric discomfort. One developed a slight rash, similar to acne, on the face; and one, whether *post* or *propter hoc*, had a severe rash of the face, neck, and hands which initially looked like urticaria and proceeded to an acute dermatitis with exudation and desquamation. In this case the drug was withdrawn, as it was in four others in which, although no marked toxic symptoms were present, there appeared to be no improvement in the incidence of petit mal. Most of the other 18 patients were anxious to continue taking the drug, as in their opinion the relief obtained from the reduction in their attacks more than outweighed the slight nuisance of the "dazzle phenomenon" or the other symptoms mentioned above.

Comment

Several important points emerge from a review of some of the literature on the subject. Tridione is said to be contraindicated in patients with severe renal or hepatic damage and in conditions in which optic-nerve disease is already present; but no residual damage to the optic nerve has been detected in patients complaining of the "dazzle phenomenon"; and "histological studies on the optic nerves and retinae of experimental animals receiving large doses of tridione over long periods have failed to reveal any evidence of damage." Several investigators have also recorded that when the drug is withdrawn weeks or months may elapse before attacks of petit mal return.

Obviously more time and greater experience are required before this drug can properly be evaluated, but there is no doubt that tridione has a pronounced inhibitory effect on petit mal and also, in the experience of American investigators, on myoclonic spasms and akinetic seizures.

Summary

The treatment by tridione of 23 cases of the petit-mal epilepsies is analysed.

Approximately four-fifths of the patients improved, but various toxic symptoms and signs were manifested in almost every case.

I wish to express my cordial thanks to the male nurses of St. David's Hospital for their keen and efficient co-operation in conducting this investigation.

The Merseyside Hospitals Council Report for 1946, *Carefree Convalescence*, is a pleasantly illustrated pamphlet with a brief account of the after-care arrangements that the Council has developed during the last twenty years. The Council has continued to acquire houses for convalescent homes, and suggests that the increasing demand for such facilities likely to rise under the National Health Service might be met in part by voluntary assistance. Four members of the Council have been appointed to the Liverpool Regional Hospital Board.

Medical Memoranda

A Fatal Case of Agranulocytosis Associated with "Tridione" Therapy

Now that tridione is being used for the treatment of certain types of epilepsy it is of interest to record the following case. This substance seems to have a high therapeutic value. Nevertheless, until extended use of it proves otherwise, it seems that it should be used with care owing to a possible depressant action on the granulocyte precursors in the bone marrow.

CASE HISTORY

A boy aged 11 had suffered from petit mal for over three years, during which time he had received amphetamine sulphate ("benzedrine") in doses of 0.01 to 0.025 g. daily. For 53 days he received four 0.3-g. tablets of tridione daily. On the 25th day of receiving tridione he developed an urticarial rash on the thighs which faded in two days. On the 51st day of tridione therapy he became ill with gingivitis and a temperature. He lived for 21 days after ceasing tridione. He received sulphathiazole (a small total amount) and penicillin by injection without any helpful effect.

When examined nine days before death he repeatedly complained of sore throat, and was very pale. The mucous membranes were a good colour, the gums were hypertrophied a little and very red, the tongue was furred and had an ulcer on the left margin. The fauces were somewhat red, but there was no lesion. The upper and lower cervical glands and a gland on the edge of the jaw were enlarged. The left submaxillary gland was enlarged and painful. The trachea was pushed to the right. There was tenderness in the right iliac fossa, where a movable tumour 2 by 2 in. (5 by 5 cm.) was felt. The spleen was slightly enlarged, as were the glands in the groins and axillae.

A radiograph of the chest revealed a shadow in the mediastinum displacing the trachea to the right. A blood count showed: Hb, 44%; R.B.C., 2,730,000; colour index, 0.8; W.B.C., 800 per c.mm. A differential count showed: all lymphocytes and no granulocytes; there were abundant platelets; after a prolonged search no "blast" cells were seen; all the white cells were mononuclear in type, and immature. A trace of albumin was present in the urine. A sternal puncture marrow smear revealed an aplasia of the erythroblastic tissue with a primary agranulocytosis.

Treatment consisted of blood transfusion and administration of pyridoxin and plexan. For two days before death he had profuse yellow diarrhoea. Later blood examination showed no change.

Abnormal Post-mortem Findings.—**Bowel:** Small yellow sloughing ulcers in lower foot or so of ileum in Peyer's patches, which were hyperplastic; gross swelling, redness, and ulceration of lower 3 in. (7.5 cm.) of small bowel, ileo-caecal valve, and caecum; multiple yellow ulcers in ascending colon; mesenteric glands +. **Liver:** Dark from free iron +. **Spleen:** Enlarged; free iron +. **Suprarenals:** Greyish with little lipid. **Brain:** Greyish, especially cortex. **Bone:** Dark-red marrow in sternum, ribs, vertebrae, femur.

Microscopical Findings from Post-mortem Material.—The tumour in the right iliac fossa showed non-specific ulceration and gross oedema. **Lumbar vertebra section:** Macroscopically the bone marrow is very red; microscopically there is some erythroblastic (normoblastic) hyperplasia, an almost complete absence of myeloid elements, and an approximately normal number of megakaryocytes.

COMMENTARY

The bone section shows that a complete aplasia of the granulocyte precursors in the marrow had supervened. The amount of sulphathiazole seems much too small to have caused this depression (over 30 g. has usually been taken in agranulocytosis due to sulphonamides). Tridione is strongly inculpated. It will be noticed that about half-way through his tridione course (25th day) the patient developed a rash. Two other children on tridione for epilepsy developed rashes and diffuse lymph-gland enlargement. In their case tridione was stopped immediately the rash appeared, and they recovered uneventfully without abnormality in the blood picture.

If during the course of tridione therapy any generalized rash, lymphatic enlargement, undue redness of gums, anaemia, or changes in the white cell count appear it would be wise to cease using tridione.

I have to thank Dr. E. A. Hunter, senior physician in charge of the case, for permission to publish and Dr. T. N. Gledhill for his report on the marrow section.

Reviews

CHILD HEALTH

Child Health and Development. By Various Authors. Edited by Richard W. B. Ellis, M.D., F.R.C.P. (Pp. 364; 49 illustrations. 18s.) London: J. and A. Churchill. 1947.

This book is a valuable addition to the growing library of books on child health, and the editor has been fortunate in his authority and special knowledge of the twelve other contributors to the volume. Of its two sections the first—on development—contains an account of anatomical, physiological, and psychological aspects of growth. We would draw attention to his masterly chapter on functional development of the foetus, by the late Sir Joseph Barcroft, and those on growth and puberty by Prof. H. A. Harris and by the editor. Prof. Ellis also contributes to this section two chapters on the newborn and on digestion, nutrition, and feeding, in which he combines in a clear and concise narrative essential scientific knowledge with practical guidance. The second section, "Social Aspects of Child Health," is considerably shorter and is mainly devoted to brief accounts of the social services and institutions dealing with healthy, "deprived," and delinquent children. It also includes a short account of the English educational system by Sir Fred Clarke.

The unfolding and complicated life of the growing child in all its aspects, together with the social problems that are involved, is a vast subject, and we cannot expect a book of this modest size to contain a full account. It is also difficult to give unity to a book of composite authorship. But all who have the care of children will welcome this book; it is a scientific manual and makes fundamental scientific knowledge available for the practical guidance and control of child health.

CHARLES McNEIL.

TREATMENT OF DELINQUENCY

The Psycho-analytical Approach to Juvenile Delinquency. Theory, Case Studies, Treatment. By Kate Friedlander, M.D., D.P.M. International Library of Sociology and Social Reconstruction. (Pp. 296. 18s.) London: Kegan Paul, Trench, Trubner and Co. 1947.

Although a steadily increasing amount of work has been done on the psychological aspects of delinquency, so much indeed that the clinical diagnosis and treatment of delinquency can now be regarded as a special branch of medical psychology, there is an astonishing dearth of reliable textbooks on the subject. Dr. Friedlander's book goes far to remedy this defect. That it is written by a thorough-paced Freudian is not altogether inappropriate, for without Freud's discoveries of the unconscious mind and of the unconscious mechanisms that regulate it the field of delinquency must have remained a *terra incognita*.

Despite the fact that the author devotes a substantial part of her book to presenting psycho-analytical theory and is throughout clearly influenced by psycho-analytical opinions, the scope and method of her presentation give evidence of first-hand clinical experience. In the section on diagnosis she clearly distinguishes unconscious factors from those social factors which not only influence the development of antisocial conduct but often determine its immediate direction. Indeed, she bases her classifications of delinquent states largely on these distinctions. Perhaps here she is least convincing. Like many analysts she pays scant attention to the clinical concept of psychopathy, a neglect which is justified only if psycho-analysts can produce more illuminating and at the same time more useful clinical classifications of character disorder. They do not appear to have done this.

Discussing treatment, Dr. Friedlander carefully distinguishes between psycho-analytic and other forms of psychotherapy and points out the limitations to applying classical psycho-analytic methods to delinquent subjects. She describes clearly the role of "transference" in the various forms of social therapy or disposal and ends with a useful outline of preventive measures. This is a good book.

EDWARD GLOVER.

EXTRACELLULAR FLUID

Chemical Anatomy, Physiology and Pathology of Extracellular Fluid. A Lecture Syllabus. By James L. Gamble. Fifth edition. (Pp. 160. 52 charts. 7s. 6d.) Cambridge, Mass.: Harvard University Press. London: Geoffrey Cumberlege (Oxford University Press). 1947.

Prof. Gamble's monograph is now established as being one of those few medical books which may truly be described as classics. As in previous editions he modestly presents the material as a syllabus of concise lecture notes based on illustrative charts; thus each section is simply headed with the number of a chart, which is explained in the text. This manner of exposition from simple line diagrams enables the author to make complex biochemical subjects easily understandable to the general medical reader. The text is brief, occupying 105 pages in large print, but characterized by remarkable lucidity and by flashes of inspired phrasing.

The main feature of the book is that the author amplifies and gives precision to Claude Bernard's great concept of the internal environment. Prof. Gamble, largely on the basis of his own research, has revealed the essential qualitative and quantitative aspects of the extracellular fluid. His separate papers and this integrated presentation illumine and make real a subject, hitherto dimly understood, which is not only important in the theory of physiology and pathology but of great practical significance in a wide range of medical and surgical disorders. To quote but one example: understanding of the normal and abnormal states of the extracellular fluid is fundamental to the proper use of fluid administration whether by mouth or by parenteral routes. The construction of the book is similar to that of former editions, but it contains some new material. The author begins by describing the normal quantity and composition of the extracellular fluid and then goes on to discuss how its constancy of composition and volume are maintained. In the later part of the book he considers the pathogenesis of dehydration and of acidosis and alkalosis and, finally, parenteral fluid therapy.

RADIOLOGY

Radiography for Medical Students. By Fred Jenner Hodges, M.D., Isadore Lampe, M.D., and John Floyd Holt, M.D. (Pp. 424; 103 plates. 56/75 or 37s. 6d.) Chicago: Year Book Publishers, Inc. London: H. K. Lewis and Co. 1947.

Confrontations. Radio-Anatomo-Cliniques. Published under the direction of M. Chiray, R. K. Gutmann, and J. S  n  que. Fascicule I. (Pp. 564. 98 figures. 370 francs.) Paris: G. Doin et Cie, Masson et Cie. 1946.

The undergraduate teaching of radiology in Britain is essentially elementary and in most medical schools does not consist of more than half a dozen lectures a year; it is debatable whether more should be packed into the already overloaded curriculum. Radiology is now sometimes taught with anatomy and physiology, and some of the pioneers argue that the combination is particularly instructive. American medicine has gone much further in this direction. This interesting volume, equally divided into accounts of x-ray diagnosis and therapy, is founded on the authors' teaching of undergraduates in the University of Michigan. There is no doubt that if the undergraduate has the time and basic knowledge to read and digest its contents he would become a wiser and better doctor, for it is well written and combines a full account of pathology with instruction in elementary radiology and physics. Judged by British standards it contains far too much, and it is not unreasonable to say that the material is so plausibly presented that there is a danger of diverting the student from more fundamental approaches to health and disease. This book is best for the postgraduate student and the beginner in radiology, but something less than this and more than the meagre pittance we consider necessary for the undergraduate is desirable and has still to be written.

The second volume is neither an essay on radiology nor a textbook but a report of the clinical, pathological, and radiological findings in 53 interesting cases of disease of the gastrointestinal tract. The authors are well known to radiologists for their interesting pre-war contributions to the study of early carcinoma of the stomach. In this series there are many such

cases; they are of considerable interest in that they show how easy it is when certain appearances are present to confuse benign with malignant lesions. With one or two exceptions all the material has been selected because the cases were difficult to diagnose. There are a few striking examples of cholecystography in which the gall-bladder failed to fill after a single dose of radio-opaque substance but concentrated normally when a second dose was given immediately after the first x-ray examination. All these case histories are well worth detailed study by radiologists.

PETER KERLEY.

PHYSIOLOGY

Précis de Physiologie. By L. C. Soula. (Pp. 1,086; 334 figures. 1,450 francs.) Paris: Masson et Cie. 1947.

Perusal of this outline of physiology confirms the significance of its dedication to Sir Charles Sherrington. The author claims—and he is probably right—that it is the first treatise on physiology in the French language to be based on the school of neurophysiology that Sherrington founded, and that it brings into accord the traditional outlook of French universities with that of the modern British medical schools. He emphasizes the large part played by new techniques in the transformation undergone by physiology in recent years. His central idea is the unity of the living animal—as he indicates in an admirable introduction—and everywhere he incorporates the recent teachings of general physiology as they throw light on the mechanisms of the human body. The book is well written, thoroughly up to date, and the diagrams are clear and instructive. It is an outline of modern physiology admirably suitable for the student of medicine.

C. LOYATT EVANS.

ASTHMA

The Diagnosis and Treatment of Bronchial Asthma. By Leslie N. Gay, Ph.B., M.D. With foreword by Warfield T. Longcope, M.D. (Pp. 334; 80 illustrations. 27s. 6d.) London: Baillière, Tindall and Cox. 1946.

Handbooks on bronchial asthma come across the Atlantic with such regularity that one is sometimes tempted to ask, "Is your journey really necessary?" A number of features give this book a certain individuality and interest for the general medical reader. Much of its content is a recapitulation of the author's own work, and it is evident that he has had wide experience in this field. The account of pollen surveys is interesting and shows how much work has been done on this important subject in the U.S.A. The chapter on pathology includes post-mortem records of 24 patients dying of asthma at the Johns Hopkins Hospital. In the last 130 pages the author describes the treatment of asthma in a practical and detailed manner, with a complete account of modern methods. The many case histories illustrating certain points in the history or treatment are an important feature of the book; they are helpful but could often be more concise without impairing their usefulness.

The arrangement of the subject matter is sometimes confusing. For example, in discussing the treatment of asthma combined with bronchial infection, the author does not mention penicillin or sulphonamide therapy, though he adequately describes them under a separate heading later on. In Chapter V the accounts of complications and differential diagnoses of bronchial asthma are inextricably mixed, and we cannot see why the effect of anaesthetics should be discussed here at all. Nor is it clear why cases of asthma starting during pregnancy are considered under the heading of "Psychosomatic Syndrome," while those whose symptoms occur during menstruation or at the menopause are regarded as due to "endocrine disorders."

It is surprising to read that Dr. Gay considers that 50% of patients with hay-fever get asthma unless properly treated; in Britain such a figure would certainly be too high. On the other hand readers in this country will be comforted to know that in the author's opinion there is no field of allergy more overrated than so-called gastro-intestinal allergy, and that the "leukopenic index"—a tedious manoeuvre for the diagnosis of specific food sensitivity—is inconsistent and unreliable.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

African Medical Handbook. By Michael Gelfand, M.B., M.R.C.P. (Pp. 202. 15s.) Capetown: The African Bookman. 1947.

An outline of medicine and hospital practice for African nurses and orderlies.

Plough and Pasture. By E. Cecil Curwen, M.A., M.B., F.S.A. (Pp. 122. 7s. 6d.) London: Cobbett Press. 1946.

The early history of agriculture and stock breeding.

Physical Fitness Appraisal and Guidance. By T. K. Cureton, Jr., M.A., M.P.E., Ph.D., et al. (Pp. 566. 30s.) London: Henry Kimpton. 1947.

A general account of physique and its measurement.

Psychological Approaches to the Biography of Genius. By L. M. Terman, LL.D., Ph.D., Sc.D. (Pp. 24. 1s. 6d.) London: Hamish Hamilton. 1947.

A presidential address delivered before the Pacific Division of the American Association for the Advancement of Science.

Genetics, Medicine, and Man. By H. J. Muller, C. C. Little, and L. H. Snyder. (Pp. 158. 12s. 6d. or \$2.25.) Ithaca, New York: Cornell University Press. 1947.

Essays on the gene, heredity, and mutation.

Treatment of Some Chronic and 'Incurable' Diseases. By A. T. Todd, O.B.E., M.B., M.R.C.P. 2nd ed. (Pp. 324. 25s.) Bristol: John Wright and Sons, Ltd.; London: Simpkin Marshall, Ltd. 1947.

Includes discussion of epilepsy, cancer, asthma, diabetes mellitus, constipation and rheumatism.

Operative Gynecology. By Richard W. Te Linde, M.D. (Pp. 751. £5 10s.) London: J. B. Lippincott. 1947.

A profusely illustrated textbook by the professor of gynaecology at Johns Hopkins University.

Hormones and Vitamins. By G. A. Stephens, M.P.S. (Pp. 315 21s.) London: George Newnes, Ltd. 1947.

Compiled to facilitate the prescribing and dispensing of hormones and vitamins.

Handbook of Child Guidance. Edited by Ernest Harms. (Pp. 751 No price.) New York: Child Care Publications. 1947.

Articles on child guidance in America by various authorities.

Psychologie der Suggestie en Autosuggestie. By Dr. Berthold Stokvis. (Pp. 263. 15 Dutch florins.) Lochem: De Tijdstroom 1947.

A monograph on the psychology of suggestion and hypnosis. In Dutch.

Lehrbuch der Pharmakognosie. By George Karsten and Dr. Ulrich Weber. (Pp. 428. No price.) Vienna: Verlag von Gustav Fischer. 1947.

A textbook of botany for students.

Modern Drugs in General Practice. By Ethel Browning, M.D. Ch.B. 2nd ed. (Pp. 223. 12s. 6d.) London: Edward Arnold and Co. 1947.

An account for medical practitioners of the more recently introduced drugs.

Clinical Dental Roentgenology. By J. O. McCall, D.D.S. F.A.C.D., and S. S. Wald, D.D.S., F.A.C.D. 2nd ed. (Pp. 343 35s.) London and Philadelphia: W. B. Saunders Co. 1947.

Describes the technique of dental radiography and interpretation of skiagrams.

Nelson Loose-leaf Medicine. Renewal pages. (No price.) Thomas Nelson. 1947.

The Biological Standardisation of the Vitamins. By Katharin H. Coward, D.Sc. 2nd ed. (Pp. 224. 16s.) London: Baillière Tindall and Cox. 1947.

Discusses the methods of standardization and their statistical evaluation.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JANUARY 3 1948

CONSULTANTS AND THE ACT

When changes in the Emergency Medical Service were announced by the Minister of Health in November, 1939, the three distinguished men who were then Presidents of the Royal College of Physicians, Royal College of Surgeons, and Royal College of Obstetricians and Gynaecologists wrote a letter to the *Journal*¹ urging the medical profession to accept the Minister's proposals. In this letter the Presidents sought to allay the fears of those who saw in these proposals the nucleus of a State Medical Service. What they then wrote is worth quoting:

"There is a suspicion amongst some doctors that the Ministry of Health may be proposing to use the E.M.S. as the thin end of the wedge for a post-war State Medical Service. We can assure such, on the highest authority, that nothing is further from the Ministry's intention and that all such fears are groundless. It may well be, of course, that after the war economic conditions may make some form of assistance to the voluntary hospitals, by grants-in-aid or otherwise, necessary, but that the voluntary system will continue there is no reason to doubt."

The Presidents' assurance was of course accepted, just as they, and quite rightly, accepted the assurance of the "highest authority." But, as Dr. Alan Wigfield subsequently pointed out,² the assurance must be "based on the assumption that this same Ministry and, indeed, this same Government will be in office when the war is over." Dr. Wigfield went on to say, "Whatever may be the case we must keep before us the possibility that sooner or later a political group for the time being in power may yet seek to introduce a State Medical Service." Dr. Wigfield has proved to be a safe prophet. While recognizing that the voluntary hospitals might need financial assistance, the Presidents undoubtedly believed that they would continue within the framework of the voluntary system. But this is not to be. The voluntary hospitals on July 5 this year will be State hospitals and each will be administered by Boards of Governors the chairmen of which are to be appointed by the Minister of Health. The teaching hospitals, too, it must be emphasized, will be State hospitals. The voluntary system will come to an end, and the State will be the monopoly owner of all voluntary, municipal, and other hospitals the Minister decides to take over on the recommendation of the Regional Hospital Boards.

No one would assert that the hospital service in this country is the best in the best of all possible worlds. The idea of establishing a hospital service on regional lines

under the influence of university centres has received widespread professional support. Some plan of efficient co-ordination in hospitals was clearly necessary. Those who were aware of the defects in the vast hospital service administered by the London County Council were, nevertheless, apprehensive of the dangers of too much planning, of too much Government. Yet it is remarkable to note that the existing owners of hospitals and the medical men who work in them have made little effective criticism of the Minister's hospital proposals in the National Health Service Act. So anxious have many been that they should not come under the control of local authorities that they have accepted with some sense of relief the translation of the municipal hospital into the State hospital. Consultants, but by no means all, have accepted the State hospital as the lesser of two evils, and all have been harked by the spectre of hospital finance from thinking further on constructive lines.

Such is the confusion of minds and of tongues in the consultant and hospital world that there is unlikely to be any effective challenge to the proposed transfer on July 5, 1948, of the hospitals of Great Britain into the ownership of the State. The implications of this revolutionary step will become more and more visible as the months and the years pass. While many consultants and specialists may accept this as an inevitable step, and some may accept it as a desirable step, we believe that the majority are still opposed to a State Medical Service. In the last plebiscite more than 50% of consultants and specialists voting voted against negotiations with the Minister under the present Act. Consultants and specialists may now consider that if there is to be opposition to the State Medical Service foreshadowed in Mr. Aneurin Bevan's Act it must come, if it is to come, principally from general practitioners and that they as consultants and specialists will have little part to play. Those who observed the difference in Mr. Bevan's manner when he addressed himself to the Consultant section of the Negotiating Committee on Dec. 2 and 3 were left in no doubt that he hoped to rule by dividing. But if we fail, because of our differences, to preserve unity as a profession we shall lose what chance is left of moulding the Health Service according to professional ideals. Apart from all this the consultant may feel himself to be in a dilemma. Firmly opposed as he may be to a State Medical Service he knows that to work in a hospital is for him the supreme necessity of his professional life. What, he may well ask, will happen to him if he sees the hospital gates shut against him because of his refusal to work in the National Health Service under the terms of the present Act? This is a dilemma, but one which we believe to be of little significance between now and July 5, 1948. In the first place the report of the Spens Committee on the remuneration of consultants and specialists is unlikely to be completed before Easter. Once the report of this Committee is published it will have to be scrutinized carefully by the profession as a whole and by the various bodies which represent the consultant world. And when the professional debates on this Committee's report have come to an end there will be the inevitable negotiations with the Ministry of Health. These are not matters that can be settled

¹ *British Medical Journal Supplement*, 1939, 2, 231.

² *Ibid.*, 1939, 2, 247.

quickly, because of the varying nature of the commitments consultants will have to undertake. It is therefore highly unlikely that consultants will be in a position to sign contracts of service before July 5, 1948, because for one thing the Government will not be in a position to offer them. They will continue their work in their own hospitals on the same basis as at present. To put it at its lowest, then, consultants and specialists should have no need to fear that by adhering to a principle they will endanger their careers or suffer financial loss. Again, if the result of the plebiscite is the same as the plebiscite of a year ago, no Minister of Health could prevent sick persons in hospitals from receiving the skilled services of such a large number of the consultants and specialists in this country.

The medical profession in Britain is now faced with the most important issue in the whole of its long history. We live in times when ideals and traditions are at a discount and when the cynic may too easily prove his case that principles may be dissolved in gold—or its many equivalents, of which power is one. Mr. Bevan has somewhat cynically dangled before the consultant the bait of no-ceiling paying beds in some State hospitals. But neither this nor his promise to exclude private nursing-homes from State control will affect those consultants—and we believe they are many—who see this Act as the first fulfilment of the Government's policy to introduce a whole-time salaried State Medical Service. This is the one central fact of the present deep conflict between the medical profession and the Minister of Health. He has refused to shift his ground and the profession must be equally resolute in refusing to shift its ground. We have a responsibility to the past as well as to the future, and we have a responsibility to the profession not only in this country but also in others. Unfortunately the World Medical Association at its meeting in September last year in Paris did not find time to hold the debate which all were anxiously awaiting—on the relationship between the doctor and the State. But in the intervals of the meeting, when medical men of close on fifty nations could discuss matters freely, this was clearly the one subject that was of the greatest concern. Medical men in the Dominions, in the U.S.A., in Scandinavia, in Europe, in India, in the Middle East, in China, are all sorely perplexed by the growing tendency of the State machine to thrust itself between the individual doctor and the individual patient. They see this intervention of the State as something essentially harmful to medicine, and they look to this country for a lead and are anxiously awaiting the outcome of the present struggle. The consultant and the general practitioner form an organic whole. Without the closest co-operation between these two the patient suffers. Both general practitioners and consultants must, therefore, resist the painfully obvious attempts being made to sever them. If those who are like-minded in their opposition to a State Medical Service stand firmly together they need remain in no doubt about the result. Mr. Bevan has the advantage that he has to make up only one mind. The medical profession is a collection of highly individualistic minds, but its problem is in essence simple, and that is to make its collective view clear on one point—whether or not it is in favour of a State Medical Service.

PENICILLIN IN BACTERIAL ENDOCARDITIS

It is surprising to recollect that until three years ago the treatment of subacute bacterial endocarditis with penicillin was strongly discountenanced in this country, the official attitude being that the large amount of the drug required could be better employed in other ways. This was perhaps true until that time, but sufferers from this disease have since been more fortunate. Encouraged by reports of its successful treatment in the U.S.A., and by the improving supply position, the Ministry of Health allocated a quantity of penicillin for this purpose at the beginning of 1945, and the control of its use was entrusted to a committee of the Medical Research Council. This committee established fourteen centres where the treatment could be carried out in accordance with a preconceived plan, and results from all centres have been reported to the committee. A report on earlier results by the secretary of this committee, Prof. R. V. Christie, appeared in this *Journal*¹ early in 1946. We now publish (p. 1) a second report in his name amplifying the previous observations not only by the inclusion of further cases but by a more searching analysis of results which have gained in significance by the longer period of the follow-up. This is the largest series of such cases on record, and it makes plain the advantages of organizing the study of a new and difficult form of treatment as a piece of co-ordinated research on a nation-wide scale. Had each institution undertaking this treatment been an independent unit, formulating its own plans and having to base conclusions only on its own experience, a good deal would perhaps have remained uncertain which is now statistically well ascertained.

In the first series of findings it was made clear that the duration of treatment was all-important, and that when this was standardized at one month the larger the dose within the limits then employed the better the results. In the earlier report the numbers on which this conclusion was based were small, but much more extensive experience has been only confirmatory. Of 58 patients given 500,000 units daily, only 6.9% died with the infection uncontrolled or relapsed; among 83 patients given 250,000 units this proportion was 16%, and in 17 receiving only 100,000 units daily it was 41%. The superiority of the largest dose is thus clearly evident, and it may be expected to eliminate the infection in at least 9 cases out of 10. On the other hand, about 35% of these initially successful cases die of heart failure or other complications, and the over-all recovery rate is thus not likely to exceed 60%. That heart failure should figure so largely as a cause of death is perhaps not so unexpected as this report seems to suggest. Unless diagnosed very early, this disease causes a degree of valvular destruction and incompetence unequalled in any other condition, and there is no evidence that healing improves the function of the valve; fibrosis and calcification may even worsen it. Whatever the achievements of chemotherapy, some of these patients must always die from the mechanical consequences of damage done before the diagnosis is made.

From this analysis there are several conclusions which emerge clearly, and other features which remain to be

explained. Prognosis is affected by five factors, of which the duration of the disease, the presence or absence of heart failure, and the state of nutrition have the most decided effect. Since the two latter depend largely on the first, they may be regarded almost as different expressions of the same thing, but they lay treble emphasis on the paramount importance of early diagnosis. The vast majority of these patients owe their predisposition to past rheumatic carditis, and a history of this disease should be borne constantly in mind. If unexplained fever in such a patient were always regarded as demanding hospital admission forthwith and a series of blood cultures, very early diagnosis would be the rule and the recovery rate would undoubtedly improve. Prognosis depends also on age, but only clearly to the extent that it is worse in patients over 50. It also depends on the site of the lesion, combined aortic and mitral disease having the worst prognosis, and septal defects the best. There were only 12 cases of septal defect, and the figures are therefore not conclusive; but the absence of valvular damage puts this form of the disease in a different category, and it would be surprising if the ultimate results were not more favourable. It also seems that the prognosis is worsened by previous treatment with penicillin; the difference is decided if relapse has occurred after a full course, but less marked if previous treatment has been inadequate.

The features which remain to be explained are failure to control infection in a small proportion of patients adequately treated, and relapse—usually within a month—in others in whom treatment was initially successful. It has also been observed that in about one-third of the patients dying after apparently effective treatment "what appeared to be living organisms" were still present in the affected valves. It might have been supposed that the degree of susceptibility of the causative organism to penicillin would be an important factor here. This is known to vary widely, the growth of some of these streptococci being inhibited by less than 0.02 unit per ml.—the approximate concentration inhibiting that of the Oxford staphylococcus—while other strains require many times this amount. The influence of this factor has been analysed in all possible detail, and it seems that unless the coefficient of resistance is 8 or more it has no observable effect. Until the cause of this sort of failure is understood it is unfortunately by no means certain that the higher dosage it is proposed to use will have any better effect. It will be noted that this study is to be continued at eight of the centres which co-operated in the earlier work: they are named at the end of the report, with an invitation that cases be sent to them.

CONDITIONED VITAMIN-D DEFICIENCY

In most children freedom from rickets is ensured if the diet contains adequate and well-balanced amounts of calcium and phosphorus, and if vitamin D is supplied either in the food or by exposure of the body to sunlight. Older subjects are similarly protected from osteomalacia, the adult counterpart of rickets. In some instances, however, calcification is defective even with a diet which appears to be satisfactory, and therapy with ordinary doses of vitamin D is unsuccessful. Among these special patients some may have lesions beyond the control of vitamin D, but others

may be cured by very heavy dosing. Thus ten years ago the American workers Albright, Butler, and Bloomberg¹ reported that a patient who had suffered from rickets for many years in spite of ordinary doses of vitamin D was cured when the dosage was raised to 450,000 i.u. daily. Subsequently Albright and his colleagues² described a series of cases in which osteomalacia was associated with steatorrhoea or with renal lesions. Some of these patients responded to massive doses of vitamin D and were considered therefore to have an abnormal resistance to the vitamin.

In this country R. A. McCance³ has recently studied an interesting case in which severe osteomalacia was traced to R.R.D. (raised resistance to D). The patient, a young woman, came under his care about eight years after the start of her illness. Her early history had been uneventful; she had been born of healthy parents and developed into a strong schoolgirl with a good record in athletics. When she was 14 years old, however, her gait became abnormal. This symptom was soon followed by great muscular weakness, which made it difficult and painful for her to walk, or even rise from a sitting posture. Primary muscular dystrophy was diagnosed and was treated with glycine, but after a slight temporary improvement the patient's condition deteriorated during the next two years until she became completely crippled. X-ray examinations now revealed decalcification of the skeleton and deformity of the pelvis. Serum phosphorus was low, but calcium was normal. When the patient was aged 18½ years, therefore, a double diagnosis of myopathy combined with osteomalacia was entertained. If any further evidence of decalcification was necessary it was soon provided by spontaneous fractures of one ulna, the pelvic bones, and extreme coxa vara. Vitamin D was now given in doses of 2,000–7,500 i.u. daily. Some progress was made, and although decalcification persisted walking became possible with the aid of crutches.

When the patient was 23 years old she came under the observation of Prof. McCance. No evidence was found of abnormalities in her kidneys or intestinal tract. A careful study of her calcium and phosphorus metabolism was made, and the balance for both was found to be negative. X-ray examinations indicated the presence of spontaneous, idiopathic, symmetrical pseudo-fractures which were clearly identical with lesions which have been described by Looser⁴ and Milkman.⁵ In spite of a good dietary history, and of exposure to irradiation as indicated by a sunburnt skin, vitamin D therapy was instituted at the high level of 500,000 i.u. daily. No dramatic change was noticed during the first 14 days of dosing, but soon afterwards both calcium and phosphorus were found to be in positive balance. The faecal excretion of calcium fell to about one-tenth of the previous level, although an increased excretion by the kidneys reduced the net gain. With phosphorus the threshold value of excretion by the kidney appeared to be increased. After therapy had been kept up for about six weeks, with a total intake of 21,000,000 i.u. of vitamin D, there was some evidence of toxic effects, and dosing was stopped. The patient's condition, however, continued to improve. After four months, x-ray examination showed considerable recalcification, with callus formation at the sites of the pseudo-fractures. Ten months after treatment recalcification was still proceeding at the rate of 5 g. weekly, while the bones appeared almost normal on x-ray examination. The final state of the patient, one year after treatment, was most satisfactory. She had no

pain, could walk with confidence, and was physically capable of earning her living. In addition to providing an illustrative and authentic example to add to our list of conditioned vitamin deficiencies, therefore, Prof. McCance has had the satisfaction of restoring to a normal life a patient who appeared to be a hopeless cripple.

CHOLERA IN EGYPT

The recent epidemic of cholera in Egypt began in September at El Kurein in the Delta province of Sharkiya. Details were given from week to week in our epidemiological notes, and some account of the measures taken to control the epidemic appeared in these columns.¹ It is now clear that during the first week the infection spread from Sharkiya to the neighbouring provinces of Dakahliya, Minufiya, and Kalyubiya in Lower Egypt, and to Ismailia and Suez. By the end of the second week there were cases in Upper Egypt, and all the Delta provinces were involved except Beheira. It was at the end of the fourth week that the curve of incidence rose steeply to the peak figure of 1,022 cases, with 581 deaths, on Oct. 20. In that week there were 4,566 cases, with 2,057 deaths.

The later course of the epidemic has recently been reviewed.² The worst day was Oct. 20, but the fifth week brought a further 5,976 cases and 2,933 deaths, and by this time 367 of the 425 villages in Dakahliya Province were affected. A decline began in the sixth week and thereafter continued steadily. During the eighth week no new areas were affected, and in the seven days there were reported 750 cases and 505 deaths. Over the eight full weeks from Sept. 23 to Nov. 16 there was a total of 20,877 cases, with 10,265 deaths—a case fatality of 49%. It should perhaps be recalled that when Egypt experienced its last cholera epidemic forty-five years ago there were over 40,000 cases, with a case fatality rate of 85%, and since the 1902 epidemic the population of Egypt has almost doubled. Once again the great majority of the cases appeared in the villages, and the disease failed to establish itself in any of the towns provided with satisfactory water supplies and adequate sewage disposal systems. It is true that the over-all incidence began to decline as soon as 80% of the population had been inoculated with anti-cholera vaccine, but whether this represents a causal relationship or merely the coincidence of inoculation and a spontaneous autumnal decline it is too early to say.

The part played by the World Health Organization in meeting a grave threat to international public health augurs well for the future. As soon as news of the outbreak was received members of the Interim Commission were consulted and authorized certain expenditure. The Division of Epidemiology advised all countries connected with Egypt by land, sea, and air routes, and every country which might possibly be concerned was provided with up-to-date information and thus enabled to take the necessary quarantine measures. The expert committee on quarantine met in Geneva, and we reported then the measures that were advised or that had already been taken by the Egyptian Government.³ So far as this country is concerned, only one individual arriving by air from Egypt was ever suspected as a possible case of cholera,⁴ and this suspicion proved to be unfounded. It should also be recorded that the mere concentration of orders for cholera vaccine through the W.H.O. Secretariat is said to have resulted in a saving for the Egyptian Government of \$125,000.

HABITUATION TO STREPTOMYCIN

Bacteria can acquire some degree of tolerance to almost any lethal agent. Unfortunately the antibiotics are far from being an exception to this: penicillin-resistant strains of certain species, particularly *Staph. aureus*, are now frequently encountered, and this subject was discussed in a leading article in the *Journal* of Nov. 29. But no such habituation as that exhibited by some bacteria on contact with streptomycin has ever been seen before; it is well recognized as a defect which severely limits the usefulness of this drug and renders its employment always something of a gamble. How rapid and extreme the change may be is illustrated in the studies of Finland and his colleagues¹ of the treatment of urinary tract infections caused by coliform bacilli. These organisms, originally inhibited by not more than 25 units of streptomycin per ml., became resistant within a few days—in one patient after only one day—to no less than 50,000 units per ml. Similar observations are features of many reports of failure in streptomycin treatment for conditions of various kinds. There has been much speculation about the mechanism by which this resistance is acquired, and some authors believe that the original bacterial population may contain a very small minority of naturally resistant cells. Alexander and Leidy² offer actual proof of this, obtained by the study of cultures of *H. influenzae* from cases of meningitis. By inoculating with enormous numbers of organisms media containing 1,000 units of streptomycin per ml. they obtained a few colonies, thus indicating that an infinitesimal proportion (1 in some billions) of cells in cultures obtained before treatment was begun possessed this high resistance. Strains from 14 patients all behaved in this way *in vitro*, although 10 of the patients had been cured by streptomycin and 4 had not, failure in 3 being attributable to the development of resistance *in vivo*. These authors believe that the outcome of treatment depends on whether one or more of these resistant cells is present when treatment is begun. The probability of this increases with progress of the disease and the greater total number of bacilli in the meninges. A patient whose strain developed resistance during treatment was found to have in the nasopharynx a year later *H. influenzae* still resistant to 1,000 units of streptomycin per ml. It is clearly only a matter of time before such strains become common, if not predominant, and a new antibiotic will consequently be needed.

A stage further than habituation has now been described, no less than the ludicrous situation in which a previously susceptible organism now requires streptomycin to enable it to grow and produce disease. Miller and Bohnhoff³ have shown previously that meningococci originally very susceptible to streptomycin can be trained within a week to withstand 75,000 units per ml. In an extension of these studies⁴ they have observed two types of resistant variant. One of these is unchanged except in its capacity for resistance to the drug; it grows normally on all media, whether containing streptomycin or not, and retains its previous pathogenicity for mice. The second type grows only on streptomycin-containing media, having lost its capacity for growth on ordinary media altogether. Its behaviour in mice corresponds: avirulent in the ordinary sense, it assumes full virulence, producing a fatal infection, only in animals treated with streptomycin. What are we to think of a chemotherapeutic agent which can become an essential growth factor for a previously susceptible organism?

PULMONARY HEART DISEASE

Pulmonary heart disease may be defined as a disorder of the heart resulting from disease of the lungs or of the pulmonary circulation. It may be acute, as in massive pulmonary embolism; subacute, as in recurrent thrombo-embolism; and secondary carcinomatosis of the lungs; or chronic.

Massive pulmonary embolism is responsible for approximately 1% of all obstetrical, surgical, and medical deaths in hospital. Thrombosis usually begins in the calves of the legs. The most useful early sign of a dangerous phlebothrombosis is a rise of the skin temperature of the affected leg. The clinical features of massive pulmonary embolism include sudden faintness and dyspnoea, subcutaneous constricting pain, an abrupt and marked fall of blood pressure, elevation of the venous pressure, and signs of profound compensatory peripheral vaso-constriction. The most certain way of making a correct diagnosis is by means of multiple chest-lead electrocardiography.¹ Treatment by heparin and dicoumarol should be instituted at once, preferably as soon as phlebothrombosis is suspected.

An interesting form of pulmonary heart disease is that due to progressive blocking of the pulmonary circulation by carcinomatous emboli or by multiple thromboses secondary to perivascular lymphatic carcinomatous infiltration.² Chorion-epithelioma or carcinoma of the stomach is usually responsible.

Chronic pulmonary heart disease is of two main types, hypertensive and anoxic, though the latter rarely, if ever, occurs alone. Hypertensive pulmonary heart disease may be of known or unknown aetiology. Known causes include schistosomiasis, periarteritis, and Buerger's disease, but the majority of cases seen in this country are of obscure origin. The sexes are equally represented. Most of the patients reported have been relatively young, and some have been children. Clinically, the disease is characterized by a preliminary variable period of breathlessness, followed by progressive congestive heart failure with a high right-ventricular pressure, low cardiac output, normal or near-normal arterial oxygen saturation, and peripheral cyanosis. There is radiological and electrocardiographic evidence of great enlargement of the right ventricle, and the pulmonary artery is dilated. Treatment is singularly ineffective and the outcome invariably fatal.

Pathological findings have been variable. Medial hypertrophy of the smaller arteries is far from constant, and when present rarely affects more than about a quarter of the vessels.³ Intimal thickening of patchy distribution is the rule, and atherosclerosis is commonly extensive. Multiple thromboses have also been described and, when old, may be difficult to distinguish from atherosclerotic lesions. Dilatation of the pulmonary artery may be associated with medial hypoplasia, as in the case described by Gold.⁴ Gilmour and Evans⁵ reported a case very similar to Gold's, and suggested that endarteritis, which seemed to be responsible for the hypertension, began as a compensatory reaction to medial hypoplasia. They thought that a vicious circle then became established, endarteritis leading to hypertension and hypertension to further endarteritis. As the authors observe, however, medial deficiencies are not believed to be the rule in cases of "primary pulmonary vascular sclerosis." Nevertheless, the idea that some congenital abnormality of the pulmonary arterial tree may be an

important aetiological factor in these cases is worth further investigation.

The anoxic type of pulmonary heart disease is characterized by a long history of chronic bronchitis or asthma, evidence of marked emphysema, cyanosis due to reduction of the arterial oxygen saturation, compensatory elevation of the cardiac output,⁶ and finally by congestive heart failure. The right ventricular pressure is raised,⁷ but much less so than in "primary" hypertensive cases. X-ray investigation again shows enlargement of the right ventricle and dilatation of the pulmonary artery. It is possible that anoxia due to emphysema is responsible for the hypertension.⁸ Aneurysmal dilatation of the pulmonary artery, of its left or right branch, or of all three may occur when medial hypoplasia is associated with pulmonary hypertension from any cause.

INTRATHORACIC NEUROGENIC TUMOURS

Neoplasms arising from nervous tissue are the commonest tumours of the posterior mediastinum. They grow from the sympathetic system or from an intercostal nerve and originate from Schwann cells, connective-tissue cells, or true nervous tissue. Most of them are benign but some are malignant, or become malignant after many years. Even those that are not biologically malignant threaten life, like all intrathoracic tumours, owing to their position; they may grow rapidly and become very large. Although these tumours are comparatively rare, they are being met with in larger numbers to-day because of the increasing applications of radiography. Susman¹ describes four cases treated by operation; two were examples of sympathetic ganglioneuromata, and two were neurofibromata arising from the sheath of an intercostal nerve. One of these last appeared in a child aged 11 who had a generalized neurofibromatosis—von Recklinghausen's disease. A huge left basal tumour eroding two ribs was removed, but several months later complete paraplegia developed and death followed. This liability of the neurogenic tumours to be associated with an intraspinal portion (dumb-bell tumour) is another reason for operative removal.

Olivier Monod,² in a study of 19 cases, states that it is better not to attempt removal, unless there is definite compression, when the tumour is a part of a neurofibromatosis because of the danger of malignant change. He points out that the neurogenic tumours are usually solitary, rounded, posterior, and subpleural; they have a poor blood supply and are easily freed and removed. Symptoms are often slight and the differential diagnosis must generally be made radiologically and depends upon the demonstration that the tumour is in the posterior mediastinum. Artificial pneumothorax often helps diagnosis by dissociating the lung from the tumour. Any pulmonary symptoms such as cough or haemoptysis are against the diagnosis of a neurogenic tumour. Monod recommends extrapleural rather than transpleural removal. Of the 17 tumours that he has removed, 11 were dealt with extrapleurally. His description of the extrapleural approach is interesting and should be consulted, but it is not entirely satisfactory except for the smaller tumours. It can be seen from his radiographs that it has been necessary to resect as many as four ribs. A transpleural approach should enable even a very large tumour to be removed after resecting only one rib, with possibly the division of one adjacent rib. Most thoracic surgeons feel that it is difficult to avoid opening the pleura when removing a large tumour, and the extrapleural approach is so apt to be cramped that they prefer a deliberate transpleural operation for almost all cases.

CANCER RESEARCH

ANNUAL REPORT OF B.E.C.C.

The Annual Report of the British Empire Cancer Campaign consists as usual of a compilation of separate reports from research laboratories, radium institutes, and hospitals, as well as from individual investigators, scattered over this country and to some extent over the Dominions. Most of the chemical, physical, and biological investigation here recorded is of a highly specialist character, employing techniques familiar only to those working in that particular field. For the twenty-fourth year in succession Mr. J. P. Lockhart-Mummery has done a useful service in editing this mass of material, but even so it is not easy to place all this work in perspective. As Lord Horder put it at the annual meeting of the Campaign recently, many pieces of the jig-saw have been found, but the masterpiece which reveals the picture is still hidden. Many of the investigations which are proceeding are long-term ones, and immediate results are not to be expected. Among the investigations described are those on the production of gene mutation in mice by dibenzanthracene, the cytochemistry of avian tumours, and the effect of sulphamezathine in inducing precocious growth in young cockerels. Every ray of light, however indirect, is presumably valuable, and one of the fascinating things about work of this kind is that no one knows at what point the whole landscape may be suddenly illuminated.

Mass Statistics

In the present report an unusually large number of cancer statistics is given. At a recent symposium on breast cancer at the Royal Society of Medicine the main controversy appeared to surround not competing methods of treatment but the interpretation to be placed upon statistics. Statistics, it is said, can be made to prove anything—even the truth. At this symposium three-year survival rates were discarded altogether. Even five-year rates were looked upon in some quarters with scepticism, and one speaker argued that the percentage claimed by one surgeon as his ten-year survival rate after operation was in excess of the ten-year expectation of life for the normal population of the same age group, demonstrating to his mind the fallacy underlying all statistics on such bases.

Whatever their exact worth, however, such statistics as are quoted in this report are of interest. The Marie Curie Hospital, for example, records 1,832 cases of cancer of the cervix treated radiologically, mostly by radium alone, since 1925. The five-year survival rate here for all the four stages is given as 45%. Attention is drawn to the difficulty of estimating the relative merits of surgery and of radiology in cancer of the body of the uterus, because comparable groups of cases treated primarily by either method are not easy to obtain. The same hospital has treated 510 cases of breast cancer over a period of 25 years, and gives the ten-year survival rate for patients in stage I as 27.2%, and for stage II, 17.6%.

Cancer of the Lung

Under the leadership of Sir John Kennaway workers in the pathological department at St. Bartholomew's Hospital have been studying the death certificates for cancer of the lung and of the larynx in men during the period 1921–38. During this period deaths attributed to cancer of the lung increased by 16.5 times in men, and by 8 times in women, though the incidence of cancer of the larynx has not risen in either sex during the last fifteen years. The examination of occupations does not disclose anything which would account for a large fraction of the increase in these deaths, and the two largest industries in the country, agriculture and coal mining, show a low incidence. The possibility of the great increase in the habit of tobacco smoking being a factor has been considered. During the period in question the consumption of tobacco roughly doubled. But the investigators do not commit themselves on this or any other factor in causation, nor indeed on whether or to what extent the increase is a real one.

The Clinical Cancer Research Committee of the Campaign presents every year a highly elaborate statistical analysis of

cases of cancer, derived from London hospitals, pertaining to some region of the body. This year attention is given to 914 cases of cancer of the colon and the results are analysed in some 40 tables. Cancer of the caecum and proximal colon is relatively more common among females, who form 60% of the cases. In cancer of the descending colon and sigmoid the proportion of the sexes is nearly equal. The mean ages of males and females in this series were 62.1 and 60.8, respectively. No significant variation was found pointing to an occupational factor among the males. The patients who consulted a doctor within three months of the onset of symptoms constituted 63% of the whole series. In 21% palliative treatment had been persisted in for more than three months before reference to a hospital. Radical operation was possible in only a little over one-third of the cases, with a mortality of 18.3%. The five-year survival rate was 31.2%.

Of the various radiobiological investigations which are recorded attention may be drawn to some interesting work carried out in the department of biophysics at Mount Vernon, which was lately brought before the British Institute of Radiology. This concerns the effect of ionizing radiations on the broad-bean root (*Vicia faba*). These roots have been found to be more easily damaged by x rays when irradiated either at 3° C. or when under the influence of hydrocyanic acid, and less easily damaged when irradiated in an atmosphere of nitrogen. The difference between the degree of growth inhibition resulting from aerobic and anaerobic radiation has been shown to be closely related to the difference in the proportion of cells in which structural changes in the chromosomes are produced under corresponding conditions of radiation.

Virus Research

The Campaign awarded some £75,000 as grants to hospitals and research workers during the year, and made a further special grant of £25,000 for virus research in relation to cancer. This special grant is to be applied over a period under the direction of the Scientific Advisory Committee. Work has been begun under its auspices in Glasgow, at the Royal Cancer Hospital; in Edinburgh, at the Institute of Animal Genetics; and in London, at the Middlesex, Royal Cancer, and Westminster Hospitals. The scheme embraces all aspects of the problem, including the use of the electron microscope and of the ultra-centrifuge, and an important part of the project is the training of workers in virus research. It takes from six months to two years for even a bacteriologist, if his previous studies have been limited to bacteria, to master the finer manipulations required in virus work. It is expected that the £25,000 will need to be considerably supplemented as the work goes on.

On the whole of this slow-moving and many-sided research Lord Horder's speech at the annual meeting may again be quoted: "We can juggle (I use the word deliberately) with carcinogens, with oestrogens, with susceptible and with resistant animal strains, with invisible 'agents' and with undefined 'factors,' but the essential causation of cancer in a woman's breast or in a man's stomach still eludes us."

Reports of Societies

RENAL FUNCTION IN DISEASE

At a meeting of the Manchester Medical Society on Dec. 3 Prof. ROBERT PLATT gave an address on "Renal Function in Disease."

He first considered the syndrome of renal failure, which was characterized by a steady deterioration in the power of the kidney to produce a concentrated urine; in the later stages the urine was pale, copious, dilute, and had a specific gravity of about 1010. When the functional power of the kidney was insufficient for the excretory needs of the body the symptoms of uraemia developed, not only because of retention of the waste products of metabolism but because of a general

disturbance of such electrolytes as sodium, potassium, chloride, calcium, and phosphates. The symptoms of uraemia—weakness, anaemia, anorexia, vomiting, wasting, drowsiness, and coma—should be clearly distinguished from the more dramatic symptoms of hypertension, such as severe periodic headache, retinal disturbances, convulsions, and paralysis, which so often co-existed and confused the clinical picture.

The first question to be discussed was why the kidney lost its concentrating power in renal failure. The underlying pathology common to all cases was loss of nephrons, and the usual explanation of the lack of concentrating power was that there was a failure of the cells of the tubules to continue their function of elaborating a highly differentiated urine. This theory was unsatisfactory. Rose Bradford showed fifty years ago that surgical removal of most of the kidney caused the remainder to secrete urine of the same type—copious, dilute, and of low specific gravity. It was inconceivable that in the circumstances the remaining nephrons should suddenly have developed tubular failure. Verney and Winton showed many years ago that an increase in glomerular pressure would also give rise to a urine of this type. More recent investigations by means of inulin and diodrast clearances had shown that the filtration fraction in chronic renal disease was high, which suggested that there was in fact a high glomerular pressure. If this was so, he suggested that it might be brought about simply by a large amount of blood perfusing a small number of nephrons. There could be no humoral mechanism involved because it was possible to have a condition of renal failure in one kidney while the other kidney was secreting a normally concentrated urine.

If it were accepted that a high glomerular pressure accounted for the character of the urine in renal failure, this did not rule out the possibility of a co-existing tubular failure in some cases, but failure of the tubule cells should give rise to glycosuria—which was never present in chronic renal disease. Moreover, the histology of chronic nephritis showed in general that in those areas where there was tubular atrophy the glomeruli were non-functioning, whereas the few remaining glomeruli were surrounded by apparently active and dilated tubules.

Prof. Platt then considered the question of oedema in acute nephritis. This was not due to hypoproteinaemia nor to heart failure. Current literature still subscribed to the view that it was due to increased capillary permeability. This view, which was never satisfactory, was based on observations on the protein content of the oedema fluid in acute nephritis which had since been discredited. Prof. Platt suggested that a low glomerular pressure would account for the scanty urine of high specific gravity which was typical of the early stage of acute nephritis, and would lead to increased reabsorption in the tubules, giving rise to fluid retention and oedema. Inulin and diodrast clearances supported this hypothesis by showing a low filtration fraction. Recent work in Manchester and elsewhere suggested that there was haemodilution with a high blood volume in the early stages of acute nephritis, a finding which supported the view that the kidney was primarily at fault and was strong evidence against the theory of capillary permeability.

Finally, Prof. Platt described briefly the recent work of Trueta, Barclay, and others, which had shown that the renal circulation could be largely diverted from the cortex into the medulla, and he discussed the bearing of these researches on reflex anuria and cortical necrosis of the kidney.

Drs. MARSDEN, ISRAELS, R. W. FAIRBROTHER, LANGLEY, DON, OLIVER, and Prof. G. JEFFERSON, F.R.S., took part in the subsequent discussion, to which Prof. Robert Platt replied.

PRIMARY STERILITY

At a meeting of the Section of Obstetrics of the Royal Academy of Medicine in Ireland, held in the Royal College of Physicians of Ireland on Nov. 7, Dr. BETHEL SOLOMONS took the chair in the absence of the new president, Dr. O'Donel Browne, who was recently elected Master of the Rotunda.

Dr. RAYMOND G. CROSS presented a series of 358 cases of primary sterility which had been investigated and treated at the

Rotunda Hospital by Dr. A. H. Davidson during the years 1935-9. He found the causes of female sterility in his series to be as follows:

	No. of Cases	Percentage of Total
Fibroids	37	10.3
Ovarian cysts	26	7.2
Retroversion	81	22.6
Endometriosis	7	1.9
Tuberculosis (genital)	12	3.3
Adhesions	39	10.8
Salpingitis (unilateral)	27	7.5
Salpingitis (bilateral)	13	3.6
Hypoplasia	26	7.2
Anovular menstruation	8 in 136	5.8
Gonococcal infection	3	0.8
Uterus bicornuate	1	0.27
Carcinoma	1	0.27

A postal survey was carried out to determine the number of patients who subsequently became pregnant; 211 patients replied, and 81 had become pregnant. This represented 38% of the known results and 23% of the total cases. He analysed in detail the pregnancies in the various conditions and compared and contrasted them with the figures from centres in Europe and America. He emphasized the good prognosis in fibroids, ovarian cysts, endometriosis, non-tuberculous salpingitis, and adhesions due to appendicitis. He further discussed the investigation and treatment of hypoplasia and anovular menstruation, and finally drew attention to the poor prognosis in cases of genital tuberculosis.

Dr. BETHEL SOLOMONS asked what was the interval which elapsed before a marriage was considered sterile? One and a half years was a fair average. Although this inquiry was into female sterility, the results were incomplete unless the number of males responsible was shown; in his clinic the male was responsible in 50% of cases. The removal of fibroids meant a cure in a large number of cases, but it should be followed by insufflation of the tubes if pregnancy did not occur within six months. While pregnancy could occur when the uterus was in retroflexion, if the marriage remained sterile and this displacement was present it should be corrected. The removal of an ovarian cyst was also followed by increased fertility. Although the results of salpingostomy were disappointing, pregnancy occurred after a skillfully performed operation in 8 to 10% of cases. Tuberculosis of the Fallopian tubes was difficult to diagnose even when the abdomen was opened. If the tubes were tuberculous, the outlook for pregnancy was hopeless. When the condition was diagnosed, ultra-short-wave therapy was indicated rather than operation. Gonadotrophic hormones were valuable and should be used. The injection of a radio-opaque substance was strongly advised. He had done hundreds of salpingographies without any fatal results and with a minimum of complications. The injection of air, oxygen, or carbon dioxide had been followed by fatal results in several cases in Dublin. He had come to the conclusion that these fatalities were due to an absence of care in technique. Carbon dioxide should be used, the gas should be allowed to percolate very slowly, the pressure should be kept low, and no anaesthetic should be used.

General Discussion

Dr. A. W. SPAIN said that in dealing with these cases it was difficult to lay down any arbitrary time. In the younger group he would be inclined to wait for three years; in older women something should be done in a much shorter time. Curettage was helpful in the diagnosis of tuberculous salpingitis but should not be undertaken in the pre-menstrual stage.

Dr. J. GALLAGHER said that he did not regard as sterile any woman under 35 years of age until after at least three years of unfertile marriage. If the patient was over 35 years of age and had been married for one or one and a half years he would advise salpingography. Most cases in the "early married group" if left alone would become pregnant anyway. He did not think retroversion was a cause of sterility at all. Rubin's test carried a definite risk, and he knew of eight deaths following this investigation.

Dr. EDWARD SOLOMONS, Dr. E. A. KEELAN, Dr. F. GEOGHEGAN, and Mr. O'NEILL also joined in the discussion, to which Dr. Cross replied.

Correspondence

National Health Service

SIR,—The *Journal* of Dec. 20, 1947, makes a reference (p. 1005) to the premature disclosure in the *Tribune*, Dec. 12, 1947, of the discussions conducted by the Minister of Health with the Negotiating Committee. In an answer in *Hansard* (Dec. 19, 1947) the Minister declared that as far as he and his colleague, the Secretary of State for Scotland, and their respective officers are concerned he "could state categorically that no disclosure of any kind had been made or condoned of the discussions, which it had been agreed with the Negotiating Committee would not be published before Dec. 19, 1947." The *Tribune* notoriously draws its inspiration from leading members of the Socialist Party. Mr. Bevan's wife is a director, and he himself was closely associated with its management up to the time of his appointment as Minister of Health.

In these circumstances I submit that it is of the first importance that the profession should be made aware of the terms of this disclosure, and I would suggest further that the *Journal* should reproduce the full text. I would emphasize particularly the passages in which the *Tribune* editorial gleefully records and in great detail how the Minister rejected all the principal demands voiced by the medical representatives, adding the dubious information that "the Minister was supported in doing so by those negotiators who were not tied to the B.M.A." The editorial accords this final meed of praise: "Politically, the Minister's firmness has been most important . . . if he had been weak in face of this reactionary profession, it would have increased doubts as to the intention to carry out a Socialist programme."

In this connexion it must be emphasized that the official "Socialist programme," published in 1943, demanded the establishment of a full-time salaried State medical service, and Mr. Arthur Greenwood (then Lord Privy Seal) in the debate on the Second Reading (*Hansard*, May 1, 1946) stated quite firmly that that demand remains the party's ultimate and unalterable aim. It must be further emphasized that the "regulation-making power," reserved to the Minister in a measure hitherto unprecedented, would enable him to impose by regulation a full-time salaried State medical service when, as he foreshadowed in a speech in the House, "the time is ripe" to do so.

The *Tribune* further reports: "Aneurin Bevan made it quite clear to the Negotiating Committee that the service will start on July 5 'with the resources at our disposal.'" This repeats exactly his reply to my question (*Hansard*, Nov. 10, 1947) in which I asked him to inform the House how many general practitioners and specialists he would require to warrant inaugurating the new health services and what measures had been taken to provide the buildings essential to carry out the undertakings of the Act. He evaded these queries with an answer which recalls a similarly defiant declaration made by the then Minister of Education in a public speech (February, 1946) that "the school-leaving age would be raised on April 1, 1947, whether or not the teachers or the classrooms were there." It would seem that the Minister of Health is similarly resolved to "launch" the National Health Service Act, 1946, whether or not the doctors or the buildings are there. In these examples both Ministers are clearly more concerned with "carrying out a Socialist programme" than with effecting any real improvement in the existing provision of education and health services. In these circumstances, I submit, the profession will be indeed mad (*quem Deus vult perdere primum dementat*) if it hands to the Minister a blank cheque for him to fill in as he will, for that is what acceptance of the present Act would in effect mean.—I am, etc.,

House of Commons.

E. GRAHAM-LITTLE.

are thousands of doctors like myself who have neither the time nor the ability thoroughly to digest and understand the National Health Service Act. The Negotiating Committee has spent a very long time digesting and discussing all the clauses of this Act. It has looked into the obvious, the not so obvious, and the frankly obscure implications of each clause.

Certain principles are considered vitally important. Do not let us be fooled by plausible statements to the effect that the Negotiating Committee is making mountains out of molehills. Let us believe our own experts, who have studied the whole matter with so much care. Let us rally round and support the Negotiating Committee. Let us unite as never before, promise in writing not to join the Service until advised to do so by the Negotiating Committee, and stick to it. By so doing we shall not harm the Service but will safeguard the future, immediate and remote. Surely it is the remote future which is in so much danger.—I am, etc.,

Bungay, Suffolk.

P. G. LEVICK.

SIR,—I am overwhelmed by the benevolence and thought for our welfare shown by that enemy of the upper and middle classes, Mr. Bevan. His attractive financial terms, his previous promises, and the exhibition of skilful skating over legally doubtful ice make delightful reading—almost a Christmas carol. But we must remember: (1) It is established that no Minister of the Crown is bound by his predecessors' promises. (2) Once we have sold our practices we have no legal say in what the purchaser does with them, and will lose all power of individual initiative.

We shall be dependent on a majority agreeing with our individual dislikes and the use of that loathsome weapon, a strike. In the meantime the basic salary can be raised at someone's discretion with a lowering of the capitation fee to balance, or just as likely, in view of an "imminent crisis," merely the latter; and we shall not be able to do a thing about it. Let us, therefore, set our faces against this modern search for easy flesh-pots and keep the standard of individual initiative flying for the rest of our great country to follow.—I am, etc.,

Cromer, Norfolk.

A. H. GREGSON.

SIR,—I am strongly opposed to the National Health Service Act but am not greatly impressed by the Negotiating Committee's case, although the Minister has avoided answering any of the main points. Why does he insist on a basic salary when a system of Government grants for young practitioners would meet all reasonable difficulties?

I feel that I could influence my neighbours and partners if I had information on the following points: (1) Are salary and capitation fee subject to "regulation" by the Minister? (2) Is actual fact how far are regulations subject to the control of Parliament? I understand that the Minister, in practice, has an almost free hand. (3) This Act is the work of one man. Therefore it is right for us to learn what we can of his character and political history before we decide to accept his word which is what he naively asks us to do. What is his record? This is business, not a tea party.

I have a son of 16 who wants to go into general practice; my father too was a G.P. and my grandfather. Why I ask the above three questions is because I find my doctor friends drawn away from consideration of principles to the Minister's statement about remuneration. If these promises are to be mere scraps of paper we shall be forced to consider the main structure of the Act—to what extent we will agree to be his servants, with no alternative employment or employer.—I am, etc.,

Havant, Hants.

M. S. DEWHURST.

SIR,—With the publication of the Minister of Health's reply to the Negotiating Committee, there is certain to be a spate of letters, discussions, and meetings on the subjects raised. May I suggest that much time and energy would be saved if members of the profession would realize that by the Minister's refusal to compromise on the seven basic principles laid down by the B.M.A. the position is entirely unchanged from the time when the plebiscite was answered by the profession earlier in the year?

It was then our feeling that terms of service could not usefully be discussed unless vital principles were conceded. As nothing has happened since then to modify the Minister's original attitude to our demands, it seems to me that Divisions and members should be warned against dissipating their efforts by discussing terms of service in a scheme which is patently unacceptable, as the liberties of the profession have not been safeguarded. Do we still hold to all we said and wrote in those days, or have we allowed ourselves to be "softened up" by the passage of time?—I am, etc.,

Tiverton, Devon.

THOMAS N. RUDIN.

SIR.—Why another plebiscite? Did not the profession indicate in the last its opposition to discussion with the Minister? Why should we allow ourselves to be added to the multitude of slaves of the State? Why present the Minister with our capital, the fruits of our labours? Why even discuss a medical service which fosters numbers and not quality?—I am, etc.,

Gerrards Cross, Bucks.

H. N. HORNIBROOK.

SIR.—It is essential that the impending plebiscite on the Health Act should provide clear information not only of the views of members of the profession but also of the action they are prepared to take in support. There are many who dislike the Act but fear to vote against acceptance on financial grounds and others who would be content to accept it but not against the will of the majority of the profession. The former must be reassured and the numbers of the latter assessed.

I therefore suggest that two questions be asked: (1) Are you in favour of the profession accepting service under the Act? (2) Are you prepared to support the decision of the majority?

The decision should be taken on the vote of private practitioners only (consultant and general), whose future is at stake. Permanent officers of the Armed Forces, salaried officials of the Ministries, county councils, and other public bodies will naturally continue their work in any event, and their votes should not influence the issue.—I am, etc.,

Finchamptead, Berks.

E. BILLING.

SIR.—The time has come when it is necessary to warn all those members of the medical profession who are inclined to regard any promise given by a Minister at the present time as necessarily permanent in the future. After a few years, when the profession is firmly in the grip of the Ministry of Health, the following can and most probably will happen: (a) On grounds of economy the remuneration of the doctors can be reduced, possibly without arbitration. (b) Private practice will ultimately dwindle, and it may happen that the Minister will issue an Order which will prohibit State medical practitioners from taking private patients. This could very well occur when the health centres are finally in operation. (c) Orders can be issued directing a doctor how he may or may not treat his patients, and he will have no more freedom or personal initiative than any other Civil Servant.

We have not forgotten that some years ago a Minister did in fact alter the terms of service, without consulting the profession, in spite of promises given beforehand. Also, we have learnt that an undertaking given by one Minister is not necessarily binding on his successors. Let us ponder these facts very carefully before we barter our heritage of freedom for a mess of pottage, however well sweetened.—I am, etc.,

Keighley, Yorks.

B. A. SLOCOMBE.

SIR.—It is rather difficult, after several years of controversy about the National Health Service Act, to see the wood rather than the trees, but it is not at the back of all our minds that this scheme is as unrealistic as prohibition in America? The ordinary middle-aged doctor who has been any good at his job finds himself with an increasing reputation and demand for his services. He has always been able to meet this situation in one of two ways. If he is as strong as a horse, he can accept more and more patients. If not, he can raise his fees and so keep his work within the limits of his sclerotic arteries. That is the true reason why we fear to see the last of private practice: it reduces the incidence of coronary thrombosis in the medical profession.

As long as a sufficient part of the populace can pay fees, a doctor's life is endurable. A 100% service, whether salaried or by capitation fee, removes any possibility of self-protection except through the bankruptcy court. It puts a premium on untutored youth and physical stamina, and a discount on greying hairs and wise judgement. It is thoroughly bad and, if introduced, is liable to suffer the same fate as prohibition.—I am, etc.,

Ashhead, Surrey

W. EDWARDS.

SIR.—The Minister's reply was more conciliatory than some of us were led to expect. But paragraph 25, "The Doctor's House," requires explanation. Why did the Minister seek advice about the citizen's right inherent in the Common Law of the land to sell what he owns, and from what will the certificate of the Medical Practices Committee protect him? Surely this unnecessary information is there to confuse or to hide something.—I am, etc.,

Haddenham, Bucks.

T. W. S. PATTERSON.

SIR.—The Negotiating Committee's case and the Minister's reply show how far we have travelled already towards first the twilight and then the night of our freedom. Gild it how he may, the Minister is asking us to become Civil Servants, shackled to a State machine, ready to obey the rules and regulations made for us by him and his successors at the Ministry of Health.

It was in May, 1946, that the Representative Body of the B.M.A. passed a resolution by 210 votes to 29 rejecting State ownership of hospitals; and another by 214 votes to 2 rejecting control over doctors with regard to the area in which they practise. In summing up the results of this meeting, the Chairman commented: "Now we have come to the time when one side or the other has to give way. A conflict is inevitable." They were fine motions, fine words, but during the eighteen months that have passed since that date, by subtle whispering propaganda and clever parliamentary tactics, the Minister has been enabled to take action so that he has made the State ownership of hospitals inevitable. During the same period he has formed committees within the framework of the Act and found medical personnel to serve on them; and among other things the functions of these committees have very much to do with the control of doctors in the area in which they practise.

The Minister is a clever psychologist, and in many respects he has jockeyed the profession into false positions. Let us remember that all his premises are based on his false assumption that the working of the Act is inevitable. Let us not make the same assumption: once we do so, we are lost. Most of us are non-political and thoughtful members of society. We are convinced in our hearts, by the tradition we inherit, that the practice of medicine must remain free if it is to prosper.

When we think of the history of our profession we realize that men of outstanding genius were always men of independent, unusual frame; and by their unique genius they made British medicine great. Surely it is only those who in their hearts regard greatness with envy who think that a State medical service is a good thing. I do not believe for one moment that such a service would appeal to first-class minds: with its pettifogging rules, its multitudinous forms, its endless negotiations, it could not do so. Instead, if this Service should come to pass, as it is envisaged by this Minister of Health, by this Government, it will come to be filled with a multitude of second-rate minds of a yes-man shape, who will make of British medicine an institution world-famous for its dull mediocrity, its small scientific exactness, the excellence of its statistics, and the envy the world over of the good bureaucrat. But this will not be the profession that could produce a Lister, a Harvey, a Moynihan, a Treves, and I do not believe that my great profession will meekly give up its freedom when the decisive day arrives.—I am, etc.,

Teignmouth, Devon.

GEORGE A. F. QUINNELL.

SIR.—"And thus, for nearly a year we have worked at the conference table to no purpose." And thus, too, do the Council add confirmation to the fears of many doctors that one of Mr. Bevan's type, creed, and expressed opinions has had from the beginning no intention of amending his Act and would prove impervious to conviction. Twelve months have

been spent in discussions with Ministry of Health officials, almost the net result of which has been to bring into sharper relief the difficulties and the pitfalls for the profession inherent in the Act. Indeed, one has the feeling that to describe such conversations as negotiations is altogether misleading and that the Committee's case could have been as well prepared in discussion among themselves with the help of legal advice, and also in half the time.

In the year that has passed all the business sides of a doctor's life as it concerns future plans have been completely held up. Behind a smoke-screen of secrecy the framework of the new Health Service has been steadily pushed forward, and doctor committee-men have taken their places among the planning authorities. Indeed, the words of the Council quoted above cannot be regarded as an overstatement, unless the delay has served the purpose of the Minister. We are now but little more than six months from the date of implementation of the Act, and still essentials and details are interlocked in a fog of uncertainty and confusion. For example, the sale and purchase of practice are defended in short and concise terms as an essential of continued freedom and efficiency, and then paragraph after paragraph is devoted to legalistic argument anent the difficulties that will arise if sale and purchase are abolished.

On which ground, then, are we prepared to join issue—on a principle of personal liberty or on the practical difficulty of working the Act as it stands? On this point it needs to be pointed out—and it cannot be too strongly emphasized—that the interests of the various sections of the profession are not identical. Of this a paramount example is again that of the sale and purchase of practice. This, though a sheet-anchor of independence and freedom as well as a guarantee of continuing efficiency to the general practitioner, is a matter of minor importance to the health officer or to the consultant. The hard truth should be faced without hypocrisy, for it is part of human nature, that men, or rather the great majority, will be more ready to disavow those principles in which they have no personal interest. Special weighting, therefore, should be allowed to the views of general practitioners in this matter.

In any event further equivocation and delay at this stage would be inexcusable and altogether intolerable. Argument and bargaining points must be put aside and the principles upon which we are prepared to stand fast decided. It is for the Council to strip themselves for action, and at the earliest possible moment to demand from the profession a plain yes or nay on simple issues which none can misunderstand.—I am, etc.,

Wirksworth, Derbyshire.

E. D. BROSTER.

SIR,—The supporters of the National Health Service have derided the present medical services as being inefficient and out of date, and have drawn much attention to the inadequate accommodation and equipment of the surgeries and waiting-rooms in doctors' private houses. The public were told that under the new scheme they would have magnificent health centres, fully equipped with x-ray apparatus and laboratories and a team of doctors who would work regular hours and not be overworked. Now that we know the details the scheme is apparently merely to put the whole nation on the panel and thus accentuate the overcrowding of the already inadequate accommodation, and there is nothing new in it at all.

Mr. Bevan would have been wiser to have followed the example of General Montgomery, who made certain that every detail of his scheme was planned before taking action.—I am, etc.,

Camberley, Surrey.

LESLIE HARTLEY.

SIR,—The doctors can accept the National Health Service Act or refuse it. The choice is theirs, they have but to exercise it. If they so will the Service cannot be forced upon them, for if 75% refuse to join on the appointed day then it cannot function, and an amending Act becomes a certainty—and that soon. The issue now before the profession is therefore remarkably simple and yet of transcendental importance, for it is nothing less than our freedom itself. On the one hand we may accept the Act as it now stands, entailing appropriation of our practices and remuneration by a basic salary—at first small to ensnare and delude us but at any time capable of increase by regulation to, mayhap, 99.9% at the will of the

Minister without reference to Parliament—in short, complete loss of our freedom and liberty of action in a full-time State salaried service. Loss of our practices inevitably implies the loss of our freedom, a disaster to both doctor and patient alike.

On the other hand we may reject the present Act by refusing in resounding majority, to join the Service and indicate this decision by a decisive negative in the forthcoming plebiscite. Such refusal, without doubt, will compel the introduction of an amending Act in which we will retain our practices and be remunerated by capitation fee alone. Thus may we assure our freedom without in any way sacrificing the interests of our patients, but on the contrary safeguarding them.

Either to accept thralldom on the appointed day or to seek service in the future under an amended Act that preserves both the liberty of the profession and the true interests of our patients is the crucial issue now before us. It must not be obscured by endless discussion of items of relatively little importance such as terms of service, remuneration, superannuation, etc. The fundamental consideration now is the future freedom of the profession or its serfdom—nothing less. That freedom is incompatible with service under the present Act. Finally, the profession itself holds the trump card, not the Minister. For pity's sake let us play it and answer in the plebiscite with an emphatic and overwhelming "NO"—I am, etc.,

Tiverton, Devon.

R. E. J. PEMBREY.

The Minister's Gloss

SIR,—Your excellent leading article (Dec. 27, 1947, p. 1037) should be studied by all members of B.M.A. Beveridge's suggestion that it was not in the interest of the State to have sick people on disability funds caused the membership of B.M.A. to rise. The Coalition Minister of Health did listen to argument and was prepared to amend his White Paper when ousted from office. The present Act was heavily opposed by the Opposition in the House, as it is by most of one's patients, be they rich or poor. Sixty-four per cent of G.P.s rejected negotiation, but three great men of the profession overruled this, provided the Minister would consider fresh legislation.

The Minister has evaded this. Why another plebiscite? A year ago, faced with a panel strike, the Minister yielded to the weapon he knows so well. I forecast that this Act will have to be amended and that the stand of the profession will earn the gratitude of millions in this country.—I am, etc.,

Newquay, Cornwall.

J. P. O'SHEA.

Congenital Pyloric Stenosis: Two Cases in One Family

SIR,—Mrs. X., aged 30, was delivered of a male infant. At six weeks the child was diagnosed as a congenital pyloric stenosis and operation performed. Feeding difficulties arose and gastro-enteritis followed, the infant dying 17 days later. Subsequently Mrs. X. was delivered of a boy and then a girl. When 39 she was delivered of an apparently normal male. Projectile vomiting appeared at the third week and one week later congenital pyloric stenosis was confirmed at operation. This infant is making good progress.—I am, etc.,

Wembley, Middlesex.

M. B. STUNGO.

The Dangers of Going to Bed

SIR,—Our congratulations are due to Dr. R. A. J. Asher for his dissertation (Dec. 13, 1947, p. 967) on the dangers of going to bed or, more correctly, being confined to bed. I should like to add one more example of the untoward and contrary result arising from prolonged rest in bed. If we wish to stenose any part of the body immobilization is the accepted procedure. It is the common practice, as mentioned by Dr. Asher, to immobilize cases of rheumatic fever for a considerable period after the fever has departed. In bygone days months in bed was considered sound practice, with mitral stenosis as the inevitable end-result—the most serious of all valvular disorders.

Any barrier erected between the left auricle and the left ventricle must have a disastrous effect on the development of the left ventricle, which carries the burden of general circulation, and this is especially true in the growing heart. The present duration of rest after rheumatic heart disease is still too long, as evidenced by the incidence of obstructive mitral stenosis seen

ADVANTAGES OVER DIGITALIS LEAF

- 1 More rapid digitalisation
- 2 Greater precision of dosage
- 3 Reduced risk of toxic effects

DIGOXIN 'B.W. & CO.'

'TABLOID' ^{WELL}DIGOXIN. 0.25 mgm. (for oral administration)

SOLUTION of DIGOXIN 'B.W. & CO.' 0.5 mgm. in 1 c.c. (for oral administration)

'WELLCOME' ^{WELL}Injection of DIGOXIN, 0.5 mgm. in 1 c.c. (for intravenous administration)

BURROUGHS WELLCOME & CO. (The Wellcome Foundation Ltd.) LONDON

The diagram summarizes the local and central actions of the drugs contained in 'Franol.' Clinical experience indicates that the combination gives more effective control than ephedrine and theophylline prescribed singly.

A noteworthy function of the 'Luminal' content is to allay anxiety: it keeps the patient physically and mentally at ease, inhibiting the sudden panic which sometimes precipitates an emergency call.

'FRANOL' (ephedrine + theophylline + 'Luminal') is supplied in packings of 20, 100, 500 tablets. The average adult dose is 1 tablet i.d.s., or 1-2 at the first warning of an attack.

Vitamin Therapy *- its uses and limitations*

ACUTE INFECTIONS

A multiple vitamin-supplement is a useful basal treatment in febrile conditions when the requirements for the water soluble factors are increased and the diet is usually restricted.

Some acute infections, moreover, are commonly associated with low body reserves of certain vitamins. Some also, like pneumonia, provide the uncommon example of urinary excretion of vitamin A, following upon functional hepatic disturbance.

For supplying the increased needs of vitamins A, B₁ and C, together with other important nutritional factors, Complevite is recommended for routine use.

COMPLEVITE A single supplement for multiple deficiencies

The recommended adult daily dose provides :—

vitamin A 2,000 i.u.	vitamin C 20 mg.	iodine } not less
vitamin D 300 i.u.	calcium 160 mg.	manganese } than 10
vitamin B ₁ 0.6 mg.	iron 68 mg.	copper } p.p.m. each

Vitamins Limited
Upper Mall, London, W.6

Twelve drops daily for the baby . . . twenty drops for the adolescent . . . and up to sixty drops for the debilitated adult. Indeed, whatever the indication for additional vitamins A and D, Adexolin Liquid may be prescribed at the *precise* dosage to meet the patient's need.*

Convalescence, malnutrition and proneness to infection of almost any kind are absolute indications for Adexolin. But to-day, when the dietary yield of vitamins A and D is seldom far from the borderline of insufficiency, there is a particular place for Adexolin among routine measures of prophylaxis.

Adexolin Liquid is almost tasteless; for infants it is conveniently mixed with the bottle feeds or with a little fruit juice.

* 1 cc. contains 12,000 i.u. vitamin A and 2,000 i.u. vitamin D

GLAXO LABORATORIES LTD. GREENFORD, MIDDLESEX BYRON 349

write for samples of MAGSORBENT with ATROPINE

which combines in Tablet form the Magsorbent brand of Magnesium Trisilicate and Atropine, uniting the antacid and adsorptive properties of the former with the spasm- and pain-relieving properties of the latter.

Formula: Magsorbent (Magnesium Trisilicate) grains 7.
Atropine Sulphate grain 1/500. Excipient q.s.

'CARBRITAL' CAPSULES

A new Sedative and Hypnotic Combination

In 'Carbrital' Capsules the rapid, but relatively brief, hypnotic action of soluble pentobarbitone is combined with the prolonged sedative effect of carbromal, and in insomnia 'Carbrital' produces slumber simulating natural undisturbed sleep of adequate depth and duration, and patients awaken refreshed and alert.

'Carbrital' is also indicated as a general sedative in neurasthenia, etc.; for pre-operative sedation; in obstetrical practice; and routinely in minor operations.

Each 'Carbrital' Capsule contains 1½ grains of soluble pentobarbitone and 4 grains of carbromal.

Issued in vials of 25 capsules.

Further particulars on request.

hospital practice. The incidence of rheumatic fever was found by Coombs to be 5 girls to 4 boys; yet the incidence of mitral stenosis in females must be in the region of 5 to 1 male. This is due to the less active life led by girls, who are seldom permitted to be out of range of the maternal eye; they sit and wait and acquire obstructive stenosis and provide most examples of auricular fibrillation in the forties. Her brother with the same diseases escapes to the playground and, despite restrictive advice, ensures that the cusps of the mitral valve are kept well apart by the vigour of his exercise, thereby securing a greater volume in flow and growth of the left ventricle. At the same time he prolongs his life.

Convalescent heart homes are not the nurseries for the cultivation of mitral stenosis that they used to be; nevertheless the introduction of the sedimentation rate has tended to increase bed rest in these cases, and mitral stenosis is actively encouraged once again. Because the sedimentation rate is increased, active endocarditis is presumed with often no justification; it might well be tonsil, sinus, or other infection. Immobilization and fibrosis are inseparable bed-mates and are to companions for growing hearts.—I am, etc.,

London, W.1.

BRUCE WILLIAMSON.

Diet and the Nation's Health

SIR.—As a humble member of the profession I note with dismay that Dr. S. K. Westman (Dec. 6, 1947, p. 926) regards the Hunterian Society and frivolity as being synonymous. A press précis can be misleading; it is probable that he has now had access to the full discussion and is a wiser man. The comparative statistics given in his letter beg many questions, but this outstanding and alarming fact is borne out—namely, the famine rages of 1919–21 responded, in the absence of adequate food or the body, to a dangerous and devastating dietary of distorted mental and moral feeding. They contributed to the downfall of their country and plunged the civilized world into chaos and economic disaster. Was the subsequent prowess of Hitler's youth in war the triumph of starvation or the thrust behind a fanatical and insatiable ambition for power? In their quest for *Lebensraum* was it not perhaps a bigger dining-room they unconsciously sought?

While I admire Dr. Westman's personal victory of mind over matter, I would remind him that his unusual menu for strength is in short supply in this country. It would be regrettable if our rowing blues were deprived of their sport because they had nibbled their oars and sucked the substance of the boats while in training. The whittling down of our larder has already caused deterioration in our morale and bred dishonesty in many a decent home. The man in the street does not need a learned society to point that out to him. The desire for a high standard of food and health is not actuated by selfishness and greed on Britain's part, but in her upholding the terms of the Atlantic Charter—"that all the men in all the lands may live out their lives in freedom from fear and want." We want butter in our guns and so avoid any continental European or Asiatic parallels of hunger and discontent.—I am, etc.,

Dursley, Gloucestershire.

ISABELLE B. S. FAYLE.

SIR.—May I add a note to Dr. F. M. R. Walshe's eloquent letter (Dec. 13, 1947, p. 971) emphasizing the importance of subjective impressions in the formulation of evidence? Sir Jack Drummond's argument seems to me to suffer from a fallacy of misplaced concreteness. He was mistaking the modern concept of nutrition for a fact, and forgetting that it is a theory still to be tested by experience. He maintained that, because we were getting all the items of diet which the modern theory of nutrition held to be necessary for our health, therefore we must be healthy. But this theory may prove to be inadequate, just as those theories of nutrition in vogue before the discovery of vitamins proved to be inadequate. It may be that from these subjective impressions which he scorns to notice new facts will emerge compelling the theory to be recast.

Of course, subjective impressions are dangerous data. The field they grow in may be thickly sown with the tares of wishful thinking. Disapproval of the Government's activities may easily squeeze itself through the gaps in our sentiment of scientific impartiality and emerge as subjective impressions concealing a grudge. This is what happened, no doubt, to those

physicians who felt that their patients were suffering from the effects of calcium in the bread at a time when the calcium was present only in their imaginations. Much laborious and honest threshing is necessary to winnow away the chaff of adventitious percepts from the grain of a new impression. But it is the impressions which supply us with new facts and which therefore ought never to be neglected.—I am, etc.,

Wallington, Berks.

E. H. HARR.

A Sign of Carcinoma

SIR.—Carcinoma of the breast frequently presents one of the stiffest problems in surgical diagnosis, and all surgeons of experience approach these cases with humility, which is understandable when pathologists tell us that never a year passes by but they see at least one breast removed in the Halsted fashion for mastitis and more than one local removal of a carcinoma in error for a benign condition.

The simple manoeuvre employed to obtain the accompanying photograph I have found after long experience to be a great help in diagnosis. If the arms are raised above the head as high as possible all the usual signs of carcinoma are increased and, if not already present, are frequently made manifest in the most surprising manner. This applies to the level of the nipples, retraction of the nipple, puckering of the skin, and even peau d'orange. In addition the palpability of the tumour to the flat hand is easier to elicit when the underlying muscles are on the stretch.

The case illustrated was referred to the out-patient department as a case of chronic mastitis, and with the arms hanging by the side the breasts were indistinguishable on inspection and the tumour was vague to the finger and impalpable to the palm of the hand. The raising of the arms above the head instantly made the diagnosis of malignancy indubitable. With chronic mastitis some puckering of the skin may be produced, but it is generally a diffuse rippling over a fair area rather than a well-defined depression such as is seen in the photograph. Feeling sure that others have made this discovery before, this simple test is nevertheless put forward in the hope that wider publicity for it will help in what must be regarded as one of the most responsible and difficult diagnoses which come the way of the clinician.—I am, etc.,

London, W.1.

A. DICKSON WRIGHT.

Staphylococcal Infection due to Penicillin-resistant Strains

SIR.—In her very interesting article (Nov. 29, 1947, p. 863) Dr. Mary Barber draws attention to the increasing incidence of strains of *Staphylococcus pyogenes* that are grossly resistant to penicillin. We have been testing between April and December, 1947, all cultures of *Staph. pyogenes* for penicillin-sensitivity, using the penicillin-ditch method with 1, 5, and 10 units of penicillin per ml. Secondary cultures had been tested throughout. Out of a total of 115 cultures of *Staph. pyogenes*, 9 (7.8%) were penicillin-resistant.

Type of Infection.—Axillary abscess, 1; otitis media, 2; furunculosis, 1; dermatitis, 1; aplastic anaemia, 1 (blood culture). The 3 other penicillin-resistant strains were grown from the throat (2) and nose swabs (1) of carriers. Considering only the strains from infected cases, 6 (5.2%) were penicillin-resistant.

In Czechoslovakia, owing to the comparative shortage, the use of penicillin, especially in the form of ointments lozenges, etc., has not been as widespread as in Great Britain. None of the cases examined had received penicillin prior to the bacterio-

logical examination. Our figures might therefore indicate a "normal" rate of occurrence (about 5%) of penicillin-resistant strains of *Staph. pyogenes*.—I am, etc.,

Košice, Czechoslovakia.

I. FRIEDMANN.

Pica for Pipes

SIR,—I recently encountered rather an unusual instance of pica (craving for unnatural food) in pregnancy, which may be of interest to your readers. The patient, a woman of 36 years, had 14 pregnancies—10 full-term and 4 miscarriages. She was recently in hospital for her fourth miscarriage, with which she had a severe haemorrhage necessitating a blood transfusion. When she was later persuaded to swallow iron in the shape of ferrous sulphate for her still present anaemia, she declared she would sooner have some clay pipes to eat.

It transpired that during all her pregnancies (and most of her married life seems to have been spent in the pregnant state) she developed a craving for clay—generally in the form of clay pipes, which were, at one time at any rate, cheap to buy and easily procurable. She has good strong teeth and evidently experiences no difficulty in the mastication of the pipes, and when she cannot obtain the latter she eats pipe-clay, as used for cleaning stairs. She remarked jocularly that her doctor used to try and dissuade her from her practice by warning that she would give birth to "stooky weans." De Lee (1947) makes a reference to the desire for clay, among other unnatural foods, by certain pregnant women.—I am, etc.,

Bellshill, Lanarkshire.

New South Wales Branch of B.M.A. and R.M.B.F.

SIR,—I hope you will allow me through your columns to record the indebtedness of the Royal Medical Benevolent Fund to the New South Wales Branch of the British Medical Association. All your readers will like to know of the great generosity of the members of the New South Wales Branch who have recently sent 360 food gift parcels to beneficiaries of this fund. This is such a warm-hearted and kindly action on the part of our colleagues overseas that I feel all members of the profession living in the home country will join with me in thanking our many friends in New South Wales.—I am, etc.,

ALFRED WEBB-JOHNSON,
President, Royal Medical Benevolent Fund.

POINTS FROM LETTERS

Splints from Spatulas

Mr. A. MACDARMID (Thames, New Zealand) writes: Take an ordinary wooden tongue spatula and introduce it into the steam in a boiling sterilizer. To do this, lower the lid so that it holds the end of the spatula against the edge of the side of the sterilizer. Leave the spatula to steam for about a minute and then take it out. It is now pliable and can be bent to the desired shape between the fingers and thumb. It should be held thus until it dries, hardens, and maintains its shape. In this way it is easy to produce a curved splint or one with several angles of 45 degrees. The splint can be padded with a strip of adhesive felt. Do not put the splint in the water or it will become too wet.

Always in the House

A DOCTOR'S WIFE writes: "My dear, I never pass a day but I think how lucky you are to have a doctor in the house." . . . So speaks one of the best patients as one is laboriously toiling up the bill with a pen, having abandoned that wretched phone to the fates for an hour. Summer isn't quite so bad, but let me sympathize with all those other poor miserable creatures whose bed-companion is the telephone and whose days are spent keeping food eternally at a reasonable temperature so that the patient may have his doctor. Then, what of the evenings? Mentally and physically exhausted, the evening surgery done, and the last sickly patient tucked safely into bed, home comes the doctor to yet another sliding meal—eight, nine, ten—whatever the whim takes him. The newspaper, a pipe, and after a few minutes loud catarrhal snores. What a cheerful evening! Woe betide the wife who inquires for medical remedies at this juncture; they are doomed to be cast off as mere psychological flights of fancy. Better to keep one's thoughts of aching chilblains or children's spots deep in the crevices of the mind. What is there to it? One often wonders; and still every medical school pours out its numerous doctors, and a thousand crazy females go and land themselves into this heaven, with a doctor "always" in the house.

Obituary

G. F. STEBBING, M.B., F.R.C.S.

Mr. G. F. Stebbing, a pioneer of radiotherapy in this country and an outstanding personality, died at his home on Dec. 22 at the age of 63, after a long and painful illness, borne with characteristic optimism and courage. Like many other medical men he succumbed to a disease to the treatment of which he had devoted himself for many years.

George French Stebbing was educated at Guy's Hospital and qualified in 1906, taking the conjoint diploma and the M.B., B.S. with honours and distinction in surgery. After completing his house appointments he told Mr. Symonds, later Sir Charles Symonds, whose house-surgeon he had been, about the kind of institutional work he would like to do. Sir Charles replied that he knew of no such place and that Stebbing must create it for himself. In 1908 Stebbing went to the Lambeth Infirmary, and with the encouragement of the late medical superintendent, Dr. A. L. Baly, he developed the clinical side there and so rapidly raised the standard of work that by 1914 Lambeth Infirmary was held in high esteem by both the local populace and general practitioners. After a period of service in the Navy he returned to Lambeth Hospital, where he remained a leading light until the day of his death. In 1934 he was elected a Fellow of the Royal College of Surgeons and recently was a member of the Council of the College. He was made a Fellow of the Faculty of Radiology in 1939.

In his early years he devoted himself to all branches of medicine and surgery, and with his tremendous capacity for work and wide reading he became a "G.P." in the very best sense of the term. Many old Lambeth medical officers and nurses have reason to thank "Steb," or the "Great White Chief" as he was affectionately termed (he wore a long white coat not usual in those days), for all he taught them. His experience was so great that his phrase, "I am quite familiar with that," disappointed many a junior colleague who felt he had produced a problem for his chief.

Some twenty-five years ago Stebbing became interested in the use of radium for the treatment of malignant disease, and in 1929 arrangements were made between the Lambeth Board of Guardians and the Ministry of Health to provide Lambeth Hospital with radium and deep x-ray therapy plant, which was to be available for the treatment of patients not only from the district but from any part of London. Stebbing visited all the principal clinics in this country and on the Continent, and the information he obtained was applied in equipping the new department. As a first-class surgeon and radiotherapist, a rare combination, he achieved great success in a great number of patients, and even when this was not possible the confidence that he inspired and the infinite pains he took with palliative measures brought comfort to many sad cases.

Stebbing will always be remembered by his contemporaries for his wide interests both inside and outside the hospital. He was a member and honorary secretary of the Radium Commission from its formation in 1929. He was chairman of the London and Counties Medical Protection Society. He was largely responsible for the establishment of the L.C.C. Clinical Research Committee and was its first chairman. From this there developed the L.C.C. Medical Society, of whose first council he was chairman. He was also for many years examiner in radiology for the Conjoint Board. He had the faculty of always being able to interest himself in anything which interested his friends and acquaintances. He was a fine team worker and was never found unwilling to see any case a colleague desired him to see. An American visitor to his clinic once described him as the "human dynamo," a tribute to his amazing energy. His direct approach to the things that mattered and his dislike of non-essentials were characteristic. He inspired complete confidence and affection in his patients and he could remember them years afterwards and what he had done for them. He was a fine lecturer and clinical teacher.

The L.C.C. Public Health Department, and particularly Lambeth, will miss him sadly, and the sympathy of the whole staff goes out to his wife, his married daughter, and the two sons, both doing medicine, who survive him.—A. D.

Sir E. Rock Carling writes: Mr. Stebbing's activities were numerous and widespread. To them all he brought the same inexhaustible energy and enthusiasm. Whatever he did he did with his might, whether as medical secretary of the Radium Commission, as chairman of Council of the Medical Protection Society, as a member of the Cancer Committee and other committees of the Ministry of Health, of the Faculty of Radiologists, or the Medical Research Council's Nuclear Physics Committee, or a dozen other bodies upon which he served. All that, too, was work of supererogation, for he filled the double post of surgeon in charge of a division at the Lambeth Hospital and radiotherapist-in-chief. Stebbing held his views with tenacity. He formed them upon what he believed to be fundamental premises and permitted no deviation. He was utterly free from self-interest, and, if not entirely devoid of ambition, his aims and object had no taint of personal advantage. He wished to exert his influence to the full in the interests of sound and safe treatment for the sick. To that extent he sought positions whence he could apply his influence, but certainly without thought of reward other than a just prestige. He was no respecter of persons but generous in his appreciation of the worth of other men whose work he could admire. His habitual cheerfulness, his sense of the comic, his genuine friendliness made him loved by those who knew him well. His transparent integrity, his professional skill and competence, his upright character, all combined to secure him the esteem and admiration of his colleagues.

Mr. Malcolm Donaldson writes: The death of George Stebbing is not only a very great sorrow to his many friends but a serious loss to the forces ranged against cancer. He was a man of outstanding character and quite fearless in expressing his views. One of the foremost radiotherapists of his time, his work in connexion with the formation of the Faculty of Radiologists is well known, but perhaps his greatest work was done with the National Radium Commission. It is no exaggeration to say that the success of the Commission was largely due to his personality and unbounded energy. Being a general surgeon as well as a radiotherapist he realized that the treatment of cancer cannot be kept in watertight compartments but must be considered as a whole. It was in connexion with the Commission that I first met Stebbing, and the more I saw of him the more I liked and admired him. He was one of the "whitest men" with whom it has been my privilege to serve.

SIR BERNARD SPILSBURY, M.B., F.R.C.P.

Dr. G. Roche Lynch writes: I would like to pay a tribute to the memory of Spilsbury and his medical work, for no one in this country during the last forty years has done more for this subject, which in turn has led to the production of adequate and accurate scientific work for evidence in the criminal courts. Many times have judges complimented him upon his clear, lucid, and accurate evidence. His energy, thoroughness, and capacity for detail are by-words, but I would like to add that the investigation only commenced in the post-mortem room, to be followed up by careful laboratory work, in turn to be followed by many hours of quiet assessment of all the material facts in his study. Thus his final opinion was made after a judicial weighing up of the facts, and it would be doing him a great wrong if it were suggested that he was a witness for the prosecution.

All his life he overworked, and in the later years he continued to do so well knowing that his heart was not strong and that prudence dictated a less energetic mode of life. It is a matter of great regret that he has not left any record of his cases, for this would be of inestimable value to future workers in this field. But his excuse would have been a genuine one—namely, he had no time. Perhaps one of the most important results of his work—one which cannot be overstressed—is his influence upon coroners. When Spilsbury commenced to work for them they employed but few trained pathologists and the work was not of a very high order. Nowadays, thanks to him, coroners have realized the importance of the employment of trained pathologists.

Spilsbury was a very human person and a delightful companion. When away in the country on a long case at the assizes one could not wish for better company and he had a gift of making friends. He was very conscious of the difficulties of the doctor who was suddenly confronted with a serious criminal case and would do everything in his power to make things easy for him.

A correspondent writes: Bernard Spilsbury's professional eminence and skill are too well known to need any eulogy—this is intended rather as a personal tribute to a great man by one who has been privileged to enjoy his friendship for more than twenty-five years. It began by our common membership of a society in which we were both interested and in which not long afterwards we had the honour of holding joint office for several years, Spilsbury later becoming one of its most distinguished presidents. He was one of the most truly modest and humble-minded men I have ever known, for although I am convinced that he knew quite well that in that branch of medicine which he had made his own he stood pre-eminent and without a rival, yet he never spoke of himself or his own achievement, and both hated and, so far as he possibly could, shunned the public notice which was inevitably thrust upon him. His complete absorption in his work was for the sake of the work itself and the advancement of the ends of justice and true knowledge, not for any personal distinction.

Spilsbury was a devoted son of Oxford and of his own College, Magdalen, where he was an honorary member of Common Room, and he used to delight in recalling his own undergraduate days. He preserved in later life much of the gaiety and almost boyish high spirits which usually belonged to much younger men, and I used often to marvel how he was able to do so under the burden of his always exacting, and often grim, professional work. His later years were greatly burdened by the loss of his two elder sons, the younger of whom had just qualified and obtained a house appointment at St. Thomas's when he was killed while on duty in one of the early air raids in the autumn of 1940. The elder son, whose health had never been robust, died in 1945. Notwithstanding these blows he still kept at his work, his capacity for which was enormous, and there was no five-day week or eight-hour day for him. What was to me one of Spilsbury's most striking characteristics as a medical witness was his great sense of fairness, and I believe that this was the general impression of the public who followed with so much interest the notable trials in which he was concerned. His evidence was always directed not to the securing of a conviction, but to the ascertainment of the truth and to the fulfilment of justice, and whenever anything was to be said in favour of an accused person one could be quite sure that Spilsbury would say it. The professions of both medicine and law will deplore his passing, and those who, like myself, have known him as a friend will be the poorer for the loss of one whom to have known as such was in itself both an education and a source of pride.

Dr. HAMISH FALCONER MASSON died suddenly, from coronary thrombosis, on Dec. 7, at the early age of 45. The third son of the late George Masson, J.P., of Kingussie, he was educated at Fettes College and Edinburgh University, where he took the M.A. in 1923. In 1926 he graduated M.B., Ch.B., and passed the examination for the F.R.C.S.Ed. in 1930. After house appointments at Preston Royal Infirmary and Kettering he was for a time in practice in Dingwall before settling in South Woodford, where he had practised for the last ten years. Hamish Masson had intellectual gifts and a personality that could have carried him to a high place among consultants, but he preferred general practice with its more personal human contacts. As a general practitioner he was immensely popular and built up a large practice in South Woodford. His handsomeness made him a conspicuous figure in any company, but no man so gifted was ever more unassuming or more tolerant towards his fellow men. His work made great demands upon him, and he never spared himself. In the last year his health gave some grounds for anxiety, but the end, when it came, was quite unexpected. On Dec. 13 a memorial service was held at All Saints' Church, Woodford Green, Essex. A crowded church was evidence of the respect and affection in which Dr. Masson was held. He will be gratefully remembered in Woodford as a good doctor.—J. B. Y.

Medical Notes in Parliament

The Medical Practitioners and Pharmacists Act received the Royal Assent on Dec. 18.

The Children Bill to make further provision for the care and welfare of boys and girls when without parents, or living away from their parents, or when their parents are unfit or unable to take care of them, and to end the Young Persons Act, 1933, and other Acts, was read a first time in the House of Lords on Dec. 18.

First readings were given in the House of Commons on Dec. 18 to the Attempted Rape Bill, and to the Animals' Bill, extending the period during which payments can be made for eradication of bovine tuberculosis.

The Report of the Committee of the Privy Council for Medical Research and the Report of the Medical Research Council for the war years 1939-45 were presented to Parliament on Dec. 18.

Veneral Disease.—On Dec. 11 Mr. SORESENSEN asked against how many men and women had complaints been lodged in respect of suspected V.D. in the Metropolitan Police area during the past twelve months. Mr. BEVAN replied that figures were not kept for the Metropolitan Police district, but in London and the Home Counties reports were received about 54 men and 875 women in 1946, compared with 37 men and 2,679 women in 1945. The number who received treatment was not available. He added that the figures showed the position was not unsatisfactory.

Health Education.—Mr. HASTINGS, on Dec. 18, asked the Minister of Health whether in view of the important part that prevention must play in the new National Health Service, and the consequent need for guidance of officers of local authorities in health education matters, he would increase the support, financial and otherwise, given by his Ministry to the Central Council for Health Education. Mr. BEVAN answered that the nature and financing of the services to be provided by the Central Council after the appointed day were still under discussion between his officers and representatives of the Council and of local authorities.

Obstetric Analgesia.—The number of cases where analgesia was provided by domiciliary midwives increased from 7,262 in 1945 to 20,507 in 1946. The number of midwives trained to give it had doubled in the current year.

Milk.—The average weekly consumption of milk under the Milk in Schools Scheme during October, 1947, is estimated to have been 280,000 gallons, which represents a weekly average of approximately 1.6 pints (908 ml.) per child taking milk.

Mass Radiography.—There are 22 mass radiography outfits working in England and Wales. For the first six months of this year the number of persons examined averaged about 50,000 a month.

Penicillin.—Current production of penicillin in the United Kingdom averages 520,000 mega units a month and is increasing. It involves no charge on public funds.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

Geoffrey Wingfield Harris, M.D., has been appointed Lecturer in Physiology, with tenure to Dec. 31, 1949, and seniority from Jan. 1, 1947.

The following degrees were conferred on Dec. 13, 1947:

M.D.—J. H. Walters, T. C. N. Gibbens, V. H. Wilson.

The following candidates have been approved at the examination indicated:

FINAL M.B.—Part II (Principles and Practice of Physic, Pathology and Pharmacology).—M. S. Adams, P. S. Andrews, J. H. Angel, C. P. Atkin, J. R. Bennett, J. G. Bennette, H. C. H. Bird, M. D. M. Bowen, P. H. Bright, M. H. Clement, D. Cooper, J. D. Cox, J. H. Cule, J. M. Frew, R. G. Gibbs, M. T. Gillies, E. H. Griffiths, N. H. Harris, O. E. F. Hodgeson, C. B. Holmes, M. C. Hudson Bennett, D. A. P. Hunt, W. N. Ingham, J. H. Inskip, J. S. Jenkins, M. C. Johnson Bennett, R. C. Jones, R. V. Knight, F. R. Lambert, M. G. H. Lewis, W. Lewis, A. A. Macdonald, J. E. Maclean, I. K. R. McMillan, R. K. Mason, F. S. Mellows, D. J. B. C. Mitchell, D. S. Price, J. C. R. Payne, A. I. D. Prentice, J. Prest, L. C. Robson, R. C. Robertson, M. H. Russell, J. D. Scott, B. E. Shairp, F. H. A. Sneath, C. G. Taylor, J. P. D. Thomas, M. B. Thompson, F. G. Tomlins, J. D. G. Turner, D. H. H. W. Walker, G. G. Walker, B. M. Watney, J. O. M. Wedderburn, J. D. W. White, D. H. L. Williams, K. L. Williams, H. L. J. Wilson, G. E. W. Woodhouse, G. M. Woodhouse. **Women:** B. Jones, A. E. Perkins.

UNIVERSITY OF EDINBURGH

At a graduation ceremonial on Dec. 19, 1947, the following degrees were conferred:

M.D.—T. M. Abbas, 2A. W. Branwood, F. S. Fiddes, S. L. Forrest, J. A. L. Gilbert, 2J. W. Rae, S. A. Rahman (*in absentia*).
Ph.D.—In the Faculty of Medicine: M. L. Bayoumi, M.B., Ch.B.
M.B., Ch.B.—A. McD. Allan, H. W. Bisset, G. Brown, Margaret W. Brown, Jean Buchanan, F. G. Cumming, I. H. P. Doherty, T. H. Donaldson, L. A. Gray, R. R. Gillies, A. Girby, G. T. Graham, Janet Hazell, L. J. M. Jamieson, H. A. Jones, H. M. Kirkpatrick, F. E. Kohler, R. G. Krause, Marjorie V. Kyte, Anne M. McCartney, B. T. Mulligan, A. M. Nelson, W. H. Nisbet, Susan B. G. Ofori-Atta, J. G. Parish, A. G. B. Poole, A. D. Ross, Jean R. W. Ross, K. Salinas, D. A. Smith, B. J. Sproule, Diana Stewart, Leila M. Wojcikzak (*née Sural*), Lesley L. D. Wood.

¹ Highly commended for thesis.

² Commended for thesis.

UNIVERSITY OF DURHAM

In a congregation on Dec. 19, 1947, the following medical degrees and diploma were conferred:

M.B., B.S.—Anna Book, H. M. Brand, H. C. Brown, J. D. Brown, J. H. Grant, Brenda M. Hilton, A. R. Horler, A. A. Lawson, K. M. Martischke, W. H. Raine, A. Rounding, J. R. W. Sinton, R. Whitfield, P. E. I. Winburn, K. M. Wood.
B.D.S.—C. H. Tonge, M.B., B.S.

UNIVERSITY OF LEEDS

At a meeting of the council held on Dec. 17, 1947, George Norman Myers, M.D., F.R.C.P., was appointed to the newly instituted post of Director of Research in Rheumatism.

UNIVERSITY OF SHEFFIELD

At a meeting of the University Council on Dec. 19, 1947, Ronald O'Rahilly, M.Sc., M.B., B.Ch., was appointed Lecturer in Anatomy and John Lewis Emery, M.D., D.C.H., Honorary Lecturer in Pathology.

The Council received the resignation by Dr. T. Jones of the post of Demonstrator in Anatomy and thanked him for his services to the University.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

At a meeting of the Royal College of Surgeons of Edinburgh held on Dec. 17, 1947, with Mr. Frank E. Jardine, President, in the chair, the following candidates, having passed the requisite examinations, were admitted Fellows: M. G. Allen-Merish, N. Ameli, G. Anderson, Una Aranha, A. J. S. Burger, B. Z. Claman, T. R. Courtney, R. D. Cowan, T. T. Davies, A. L. Deacon, J. L. Douglas, W. Drummond, G. E. Dunkerley, J. R. Elder, C. D. Falconer, W. I. Giffen, J. S. Glennie, J. T. Gray, L. M. Greene, G. I. Henderson, N. G. C. Hendry, S. Henson, F. G. Hibbert, W. P. Hirsch, J. Hughes, T. B. Hutton, H. B. Jackson, I. Jacobson, J. Jankowicz, J. H. Jordan, P. F. King, R. G. R. Langford, M. D. Leitch, G. Lester, A. M. Loughran, A. Lurie, W. A. McAlpine, J. N. McCaggie, V. V. McCusker, A. McDougall, J. A. Macfarlane, J. C. McFetridge, K. MacI. MacKenzie, G. C. McKinlay, L. A. McShine, W. A. W. Maney, M. J. Maxwell, L. Mirkin, W. Murdie, D. S. Murray, J. F. Neil, M. W. Paterson, R. H. Purnell, I. Ramamurthy, J. I. Rossman, J. E. Rowlands, M. P. Shapiro, E. G. Shaw, R. H. Simpson, S. R. Sinclair, M. S. Sindhu, T. S. Stewart, C. R. Strother-Stewart, S. D. Stock, I. S. D. Thomson, J. I. Thomson, A. K. Toufeeq, W. A. L. Tucker, H. P. Watson, A. Webster, T. B. Whiston, G. W. Wigg, H. W. G. Williams, H. Williams, J. E. Wilson, H. C. Worrall, Margaret P. Yeoman, G. Young, I. S. Young, H. Zalin.

SOCIETY OF APOTHECARIES OF LONDON

Meetings of the Court of Assistants of the Society were held on Oct. 28 and Dec. 16, 1947, with the Master, Prof. E. C. Dodd, F.R.S., in the chair. Past Masters' Medals were conferred upon Dr. J. Prescott Hedley and Dr. Hugh Powell. The reports of the deaths of Dr. Russell E. Palmer, a retired Member of the Council and Group Captain Henry Cooper, late Clerk and Registrar of the Society, were received with great regret. The following were appointed representatives of the Society: on the General Medical Council, Dr. Hedley; on the Committee of Honour of the Fourth International Congress of Otolaryngology, Prof. Dodds; on the Central Council for District Nursing in London, Mr. George Wynn Williams. Dr. Archibald Gilpin was appointed Archivist to the Society in succession to the late Dr. Cecil Wall.

The diploma of M.M.S.A. was granted, upon examination, A. M. Michalewsky.

The diploma of L.M.S.S.A. was granted, upon examination, the following successful candidates: J. N. Phillips, H. R. Mohammed, F. A. R. Bateman, H. Burns-Preece, A. A. Collis, M. E. Cowan, J. J. Cowan, G. R. Davies, R. Worsley, R. J. Helyer, D. M. H. Bickman, D. G. Buchanan, J. C. Bradley, P. Benham, D. G. Walton, Furness, J. M. Scott, K. Y. Khong, D. M. Strange, E. Wales, C. Burrows, H. S. Baar.

An effective new antidote for arsenic, mercury and gold poisoning

ORIGINALLY INTRODUCED during the war for the treatment of Lewisite gas poisoning, B.A.L. has now been applied to the treatment of poisoning by other arsenical compounds as well as mercury and gold salts.

Injection of B.A.L. consists of a sterile 5 per cent. solution of 2, 3-Dimercaptopropanol in arachis oil containing 10 per cent.

Benzyl Benzoate. Supplied in boxes of 12 x 2 c.cm. ampoules.

B.A.L.

'MYANESIN'

The new muscle relaxant

'Myanesin' has now been administered in some five thousand cases. Its value as an abdominal relaxant during surgery has been abundantly confirmed.

'Myanesin' was discovered in the B.D.H. Research Department. It is an entirely synthetic substance of known and constant chemical composition [α : β - dihydroxy - γ - (2 - methylphenoxy) - propane].

'Myanesin' is now available as a 10 per cent. solution in ampoules of 10 ml. issued in boxes of 3 and 12 ampoules.

EVANS

For sustained control of gastric hyperacidity

NOVASORB

(Hydrated Magnesium Trisilicate)

Novasorb provides for sustained control over gastric hyperacidity without producing an alkaline condition in the stomach. It thus presents a desirable improvement over the older antacids, where control is limited to the immediate reaction and where continued administration of excess alkali may induce alkalosis.

High adsorptive properties

Will not give rise to alkalosis

With suitable doses, does not destroy peptic activity

A safe antacid for general use

The Novasorb brand of hydrated magnesium trisilicate was developed and introduced by Evans Fine Chemical Works and is based on original observations and clinical trials. (*Brit. med. J.*, 1936, 1, 143, 205, and 254).

Issued in Powder and Tablet form

FINE CHEMICALS, BIOLOGICALS, PHARMACEUTICALS

I-SO-GEL, a granular preparation of certain dried mucilaginous seeds, has the property of reproducing the normal stimulus to intestinal peristalsis by increasing the intestinal bulk, through absorption of water in the alimentary canal.

I-SO-GEL contains no purgatives and is a purely natural laxative with a smooth mechanical action, specially suitable for the constipation of diabetics.

It is valuable also in mucous colitis, dysentery, hæmorrhoids, and intestinal flatulence. After the performance of colostomy, I-so-gel gives excellent results by solidifying the faeces.

In bottles at 4/6 and 16/10 each, including Purchase Tax.

GRANULES

ALLEN & HANBURY'S LTD, LONDON, E.2

Following the early diagnosis of pregnancy, one of the more commonly expected minor complications is the 'train of gastric symptoms referred to as morning sickness.

Gastric discomfort, nausea, retching or actual vomiting are all too common in the early months. Of particular assistance during this period is a regular dose of 'BiSoDoL' on waking in the morning.

The alkaline composition of 'BiSoDoL' controls excessive acidity; the magnesia present is mildly aperient, while the enzymes, papain and diastase it contains assist the digestive processes. Pleasantly flavoured with peppermint oil it is easily taken in milk or water.

FORMULA

Bismuth, subnit., Mag., carb. lev., Sod. bicarb., Papain, Diastase, Ol. menth. pip.

BiSoDoL Limited · Chenies Street · London · W.C.1

DEEP DARK SECRET

Suffering in silence because of a natural reluctance to reveal any abnormal rectal condition, the patient with haemorrhoids is additionally inhibited by vague fears of major surgery and "the knife".

Having finally exposed his secret to the physician, the patient may frequently be spared further pain and discomfort by the use of Anusol* Haemorrhoidal Suppositories.

Providing relief through their decongestive and lubricating qualities, Anusol Haemorrhoidal Suppositories diminish pain, lubricate the ano-rectal mucosa and discourage "fear retention" followed by straining.

Anusol

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Dec. 13.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

Polio-myelitis

For the first time since the peak figure of the week ended Sept. 6, notifications of poliomyelitis in England and Wales for the week ended Dec. 13, 77 (70), and of polio-encephalitis 7 (6), were slightly higher than in the preceding week. Figures for the week ended Dec. 6 are given in parentheses. The only county showing a definite rise was Somerset 5 (0), otherwise the increases were in ones and twos and were scattered throughout the country. A further fall was shown, however, in the figures for the week ended Dec. 20, when there were notified 55 cases of poliomyelitis and 5 cases of polio-encephalitis.

Discussion of Table

In England and Wales infectious diseases were more prevalent during the week. A rise in the number of notifications was recorded for every disease except scarlet fever, which declined by 88. There were increases in the incidence of measles 580, whooping-cough 249, acute pneumonia 193, diphtheria 28, cerebrospinal fever 18, dysentery 13, and typhoid 10.

The largest increases in the local incidence of measles were Yorkshire West Riding 88, Cornwall 46, Glamorgan 74, and Staffordshire 70; the only large decrease was Surrey 86. The incidence of whooping-cough increased in each region except in the south-western counties and Wales; the most notable rise was Lancashire 62.

The largest increases in the notifications of pneumonia were those of Yorkshire West Riding 42 and Lancashire 30. The only significant variation in the local trends of diphtheria was a rise of 14 in Essex. No changes of any size occurred in the local trends of scarlet fever.

Of the 10 cases of typhoid fever 6 were notified in Lancashire, Warrington R.D. An outbreak of dysentery involving 9 persons was reported from Sussex, Petworth R.D. A rise in the notifications of dysentery occurred in Yorkshire West Riding, from 3 to 27; the cases were scattered throughout the county.

The notifications of acute poliomyelitis after declining for thirteen consecutive weeks showed a rise of 7. The chief feature of the returns for poliomyelitis was a rise from 17 to 32 in the combined areas of London and the south-eastern and south-western counties.

In Scotland increases were recorded in the notifications of measles 39 and diphtheria 29, and decreases were reported for scarlet fever 41, acute primary pneumonia 21, and whooping-cough 15. A small increase in the incidence of diphtheria was recorded in most regions; the largest local rise was in Glasgow, where the cases rose from 16 to 30.

In Eire there were decreases in the incidence of scarlet fever 23, whooping-cough 19, diphtheria 14, and measles 12. In contrast to the general trend increases in the notifications of measles were recorded from Wicklow, Bray U.D. 15, Wexford, Enniscorthy 16, and Dublin C.B. 16.

In Northern Ireland the notifications of measles increased by 19 and those of scarlet fever fell by 15. The rise in the notifications of measles was mainly due to an outbreak in the urban district of Portrush with 15 cases.

Medical News

I.S.T.D.

A course of six lectures on "Delinquency and the Educator" will be given by Miss Barbara Low at the Institute for the Scientific Treatment of Delinquency, 8, Bourdon Street, London, W., on Jan. 27 and Feb. 3, 13, and 24, and March 2 and 9, 1948, at 6.30 p.m. The fee for the course is 15s. (single lecture, 3s.).

Ulster Medical Society

After a lapse of nine years the Ulster Medical Society held its Annual Dinner on Dec. 11, Mr. G. R. B. Purce, the president, being in the chair. The attendance of Fellows and guests was limited by Ministry of Food regulations, and many who would have welcomed the opportunity of resuming this happy annual occasion were unable to be present. The Honorary Fellowship of the Society was conferred upon Prof. F. J. Browne, Mr. James A. Craig, Mr. S. T. Irwin, Prof. C. G. Lowry, Mr. Howard Stevenson, M.P., and Sir Henry Tidy.

Tubercle

The Tuberculosis Association has adopted *Tubercle* as its official organ; the January issue of the journal carries notice of the change on its cover and includes Dr. Frederick Hcaf's Presidential Address to the Association.

H.S.A. Scholarships for Nurses

The Hospital Saving Association will award scholarships in 1948 for trained nurses as follows, the approximate values being shown: Nursing administrators, £196 each; nursing administrators (public health), £196 each; nurse dietitians, £340 each; sister tutors, £203 each; tutors to health visitors, £203 each; health visitors, £126 each; industrial nurses, £143 each; midwife teachers, £78 each. The H.S.A. will later determine the number of each kind of scholarship to be awarded and reserves the right to withhold any scholarship if there are too few suitable candidates. The scholarships will be available for the courses at any of the recognized training centres. They are open to nurses who (a) are registered on the general part of the State Register and (b) have graduated in a voluntary or local-authority hospital within the area of King Edward's Hospital Fund for London. Applications must be made before Jan. 31, 1948. Particulars may be obtained from: The Director in the Education Department, Royal College of Nursing, 1a, Henrietta Place, Cavendish Square, London, W.1.

Donations to Institute of Child Health

The province of Natal has recently given £106,888 to the Institute of Child Health of the University of London, and an anonymous donor has given £5,000 to establish a lectureship in memory of the late Mr. A. Simpson-Smith, formerly surgeon to the Hospital for Sick Children, Great Ormond Street. The Institute was established in 1946 and is accommodated at the Hospital for Sick Children. The demand for postgraduate teaching considerably exceeds the facilities available, but it has been met in part by clinical out-patient teaching at the Queen Elizabeth Hospital for Children, Hackney Road. Teaching on the new-born baby is given at the British Postgraduate Medical School, Hammersmith. The Institute also conducts research at the Great Ormond Street Hospital, and recently a genetics department has been established to study hereditary disorders. It is proposed to have a new building for the Institute as near as possible to the Great Ormond Street Hospital. These munificent gifts are especially timely, for plans are being made to expand the Institute.

COMING EVENTS

Socialist Medical Association

An inaugural meeting of the North-west Middlesex Branch of the Socialist Medical Association will be held at Wembley Town Hall on Jan. 8 at 7.30. Dr. Eileen Warren will speak on "The Socialist Medical Association and the New National Health Service."

St. George's Hospital Medical School

A series of neurological and psychiatric lecture-demonstrations, which began at St. George's Hospital Medical School, Hyde Park Corner, London, S.W., on Jan. 1, will be continued weekly on Thursdays, at 4.30 p.m., until March 18. The lecture-demonstrations are open to all medical practitioners and senior students, without fee.

National Congress on Cancer

The third National Congress on Cancer will be held in Havana from Feb. 23-28, 1948. Further information may be obtained from the Organizing Committee of the Anti-Cancer League, whose offices are at F.Y. 29, Vedado, Havana. Among other contributions papers will be read at the Congress on cancer of the lung, bladder, and uterus.

SOCIETIES AND LECTURES

Sunday

LONDON JEWISH HOSPITAL MEDICAL SOCIETY.—At Woburn House, Tavistock Square, London, W.C., Jan. 4, 3 p.m. "Some Chemical and Biological Properties of Antibiotics." E. Chain, M.A., Ph.D.

Tuesday

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, W.C.—Jan. 6, 5 p.m. *Pathological Demonstrations.* Dr. I. Muirhead.

Thursday

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, Hyde Park Corner, London, S.W.—Jan. 8, 4.30 p.m. *Neurological Lecture-demonstration.* Dr. A. Feilberg.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, W.C.—Jan. 8, 5 p.m. "Cutaneous Tuberculosis." Dr. G. B. Dowling.

Friday

LONDON CLINICAL HOSPITAL, Victoria Park, E.—Jan. 9, 5 p.m. "Spongiotic Dermatitis." Dr. J. Smolár.

ROYAL MEDICAL SOCIETY, 7, Melbourn Place, Edinburgh.—Jan. 9, 8 p.m. "Some Physical Signs in Clinical Surgery." Address by Mr. Hamilton Bailey.

APPOINTMENTS

LONDON COUNTY COUNCIL.—The following appointments have been made at the hospitals indicated in parentheses: *Senior Physicists (Superintendents):* J. C. Evans, M.R.C.S., M.R.C.P. (St. Charles); W. Feldman, M.D., M.R.C.P. (St. Giles); W. G. Sears, M.D., M.R.C.P. (Mile End); B. A. Young, M.D., M.R.C.P. (St. Alfege's). *Physician Superintendents:* J. S. Anderson, M.D. (Grove); J. V. Armstrong, M.D. (Brook); H. S. Banks, M.D., F.R.C.P. (Pai); N. D. Begg, M.D. (North-Eastern); F. J. Bentley, M.D., F.R.C.P. (High Wood Hospital for Children); J. C. Blake, M.B., B.S. (South-Western); W. C. Fowler, M.D. (Pinewood Sanatorium); W. Gunna, M.B., Ch.B., F.R.C.P. (North-Western); W. H. Kelleher, M.D. (Western); M. H. Lugg, M.D. (Grove Park); G. W. Ronaldson, M.D. (Eastern); W. E. Snell, M.D., F.R.C.P. (Colindale); I. Watt, M.D. (King George V Sanatorium). *Surgeon Specialists (Superintendents):* W. P. Greenwood, M.D., F.R.C.S. (Bethnal Green); R. A. V. Lewys-Lloyd, F.R.C.S. (St. Olaves); J. McN. Milloy, F.R.C.S. (St. Mary Abbot); J. E. Piercy, F.R.C.S. (New End); J. R. M. Whigham, F.R.C.S. (St. Andrew's). *Senior Physicists (Deputy Superintendents):* H. C. Aston, M.B., Ch.B., M.R.C.P. (Bethnal Green); R. D. Green, M.D., M.R.C.P. (Paddington); T. St. M. Norris, M.B., B.Chir., M.R.C.P. (Archway Group of Hospitals, Highgate); D. W. G. Smith, M.B., Ch.B., M.R.C.P. (St. Andrew's); M. Toohy, M.D., M.R.C.P. (New End); C. E. W. Wheaton, M.D., M.R.C.P. (Lambeth). *Assistant Senior Physician (Deputy Physician Superintendents):* G. E. Breen, M.D. (Brook); J. W. Healy, M.D. (Eastern); L. J. M. Laurent, M.D., M.R.C.P. (Park); W. J. P. Lillis, L.R.C.P. and L.M. (Western); J. J. McCann, M.B., B.S., M.R.C.P. (Pinewood Sanatorium); J. C. J. McEntee, M.D., M.R.C.P. (Grove); D. Porter, B.M., Ch.B. (King George V Sanatorium); A. M. Ramsay, M.D. (North-Western); W. F. Richards, M.B., B.Ch., M.R.C.P. (High Wood); R. Swyer, M.R.C.S., L.R.C.P. (North-Eastern). *Surgeon Specialists (Deputy Superintendents):* H. L. Cochrane, F.R.C.S. (Fulham); G. S. Ferraby, M.S., F.R.C.S. (St. Charles); J. Gabe, F.R.C.S. (St. Alfege's); J. C. Gillies, F.R.C.S. (Hackney); S. W. Holmes, F.R.C.S. (Mile End); I. W. Matheson, F.R.C.S. (St. Giles); I. L. Price, F.R.C.S. (Archway Group of Hospitals, Highgate). *Senior Physicists (Deputy Superintendents):* M. B. S., M.R.C.P. (I); P. Harvey, M.D., M.R.C.P. (St. Olaves); H. E. S. Pearson, M.D., M.R.C.P. (Archway Group of Hospitals, Highgate). *Surgeon Specialists:* T. J. Ester, F.R.C.S. (Lambeth); A. N. McCrea, F.R.C.S. (Dulwich); H. K. Vernon, M.S., F.R.C.S. (St. James); R. H. Metcalfe, M.Chir., F.R.C.S. (St. James, and Queen Mary's Hospital for Children, Carshalton); R. C. F. Caterall, M.Chir., F.R.C.S. (St. Alfege's, and Queen Mary's, Sidcup). *Assistant Surgeon Specialists:* R. Glyn Thomas, F.R.C.S. (Queen Mary's Hospital for Children, Carshalton, and St. James (deputy at the former)).

JONES, T. B., M.R.C.S., L.R.C.P., D.P.M., Deputy Medical Superintendent, Royal Eastern Counties Institution, Ltd., Abbeygate House, Colchester.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Bintcliffe.—On Dec. 19, 1947, to the wife of Lieutenant-Colonel E. W. Bintcliffe, M.B.E., M.S., F.R.C.S., a son.
Holloway.—On Dec. 19, 1947, at Selly Oak Hospital, Birmingham, to Dulcie (née Callis), wife of Dr. H. J. Holloway, a daughter—Anne Michele.
Laurie.—On Dec. 17, 1947, at Gwyn Mor Nursing Home, Cardiff, to Sybil, wife of Lieutenant-Colonel W. Laurie, D.S.O., I.M.S., a son.
Peberdy.—On Dec. 25, 1947, at 5, Tankerville Place, Newcastle-upon-Tyne, to Mary (née Laws), wife of Dr. Geoffrey Peberdy, a sister for Karen—Nes Marion.

DEATHS

Bentley.—On Dec. 24, 1947, Robert Moorhead Bentley, M.B., B.Ch., of Westfield House, Heckmondwike, Yorks, aged 82.
Broughton-Alcock.—On Dec. 23, 1947, at Chiswick, William Broughton-Alcock, M.B.
Collins.—On Dec. 23, 1947, Henry Nathan Warner Collins, M.D., D.M.R.I. of 50, Putney Hill, London, S.W.
Davies.—On Dec. 16, 1947, at 176, Hamstead Road, Handsworth, Birmingham, Arthur James Davies, M.B., Ch.B., M.R.C.P., aged 50.
Golfein.—On Dec. 17, 1947, at 7a, Basing Hill, London, N.W., Bernard Golfein, L.S.A., aged 76.
Ingram.—On Dec. 20, 1947, at 42, Westby Road, Bournemouth, Arthur Charles Ingram, M.D.
Jobson.—On Dec. 19, 1947, at St. Thomas's Hospital, London, S.E., Dr. William Charles Jobson, M.B., Ch.B., Colonial Medical Service.
Johns.—On Dec. 23, 1947, at Netherleigh, Lansdown Road, Cheltenham, John Francis Johns, M.D.
Johnstone.—On Dec. 20, 1947, at King's College Hospital, London, S.E., Frederick John Carlyle Johnstone, M.D., late Colonial Medical Service.
Jones.—On Dec. 22, 1947, Herbert Saunders Wansborough Jones, M.B., C.M.
Masina.—On Dec. 17, 1947, at Masina Hospital, Bombay, Ardeshir Homay Masina, M.D., M.R.C.P., aged 36.
Mitchell.—On Dec. 18, 1947, John Malcolm Lamont Mitchell, M.B., Ch.B., of 10, Claremont Gardens, Upminster.
Pileher.—On Dec. 26, 1947, at Thirty Trees, Ashleat, Surrey, Edgar Montagu Pileher, C.B., C.B.E., D.S.O., F.R.C.S., Major-General, late R.A.M.C. aged 82.
Ramsden.—On Dec. 23, 1947, at Briarfield, Dobcross, Oldham, Herbert Ramsden, M.D., J.P.
Robson.—On Dec. 19, 1947, at Inverness, Briton Smallman Robson, M.B., B.S. Surgeon Captain, R.N., retired.
Sealy.—On Dec. 18, 1947, at Old Orchard, Chardstock, Humfrey Newthar Sealy, M.R.C.S., L.R.C.P., Colonel, late R.A.M.C., aged 60.
Sheldon.—On Dec. 25, 1947, Arthur Izod Sheldon, M.R.C.S., L.R.C.P. Surgeon Captain, R.N., of Landrail, 1, Cranewater Park, Southsea.
Siebling.—On Dec. 22, 1947, at 38, Telford Avenue, London, S.W., Gertrude French Siebling, F.R.C.S., F.F.R.
Stinger.—On Dec. 13, 1947, at Port-Alberni, B.C., Wilfred Isaac Stinger, M.D., M.C.P.S.
Wagner.—On Dec. 17, 1947, at 1, Albemarle Villas, Stoke, Robert E. Wagner, M.B., B.Ch.
Watson.—On Dec. 24, 1947, James Watson, M.B., C.M., of Hollybush Thimswall, Wirral.
Willoughby.—On Dec. 17, 1947, at 2, Church Street, Southwell, James Frederick Darby Willoughby, O.B.E., M.R.C.S., L.R.C.P., aged 91.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Chronic Mastitis

Q.—What treatment do you suggest for chronic mastitis, and what is your opinion of injections of testosterone propionate in these cases?

A.—The hormone treatment of chronic mastitis is based on the view that the condition is due to excessive stimulation by endogenous oestrogens. Testosterone propionate, if given in large doses, can prevent ovarian follicle development and ovulation by inhibition of the pituitary gonadotrophic hormone secretion. Such a dosage—in the neighbourhood of 200 mg. weekly—is likely to produce hirsutism and acne. On the favourable side it results, in many cases, in relief of pain, and sometimes in disappearance or diminution of painful nodules. Smaller doses than this—for example, 25 mg. injected twice weekly—may ameliorate the symptoms of chronic mastitis without producing amenorrhoea or virilism. It is noteworthy, however, that Spence (*Lancet*, 1939, 2, 820) found that pain was relieved in 13 of 24 patients by injection of sterile olive oil, indicating the importance of a psychological factor in some cases. Nevertheless, both he and Atkins (*ibid.*, 1940, 2, 412) found that benefit from androgens was probably real, although the effect was not permanent.

Tallqvist Method of Haemoglobin Estimation

Q.—As a matter of interest, I have made a rough Tallqvist estimation of haemoglobin on my panel patients. Of 200 estimations only one is over 60%; many are as low as 40%. Can this be due to rationing?

A.—The Tallqvist method of estimating haemoglobin is generally agreed to be grossly inaccurate, and incidentally to give low values. The method is so unreliable that it is impossible to interpret the information supplied. It seems most unlikely that anaemia is becoming widespread, since a committee of the Medical Research Council which carried out a large-scale investigation in 1943 found no apparent increase in anaemia despite rationing.

Vaginal Pruritus

Q.—Can there be any connexion between oestrogen treatment and vaginal pruritus? A woman aged 38, living in India, has for the past year suffered from pruritus limited to a small patch of erythema on the posterior vaginal wall just internal to the carunculae hymenales. The itching is sporadic, occurring once a month and lasting about ten days, but is unconnected with menstruation. During an attack the erythema does not spread to the surrounding tissues. Glycosuria and cervical erosion have been excluded. The patient has had courses of oestrogen by injection, repeated at intervals of two to three months, for sterility. These have now been discontinued with no change in the pruritic condition. What further treatment is recommended?

A.—Although allergic reactions to various oestrogens are described (see Zondek and Bromberg, *J. Obstet. Gynaec. Brit. Emp.*, 1947, 54, 1) the clinical features of this case do not suggest this as a likely explanation. The strictly limited nature of the lesion prompts a search for something different from the usual causes of diffuse pruritus vulvae—for example, trichomonas vaginitis, achlorhydria, anaemia, avitaminosis—although these should be excluded. Has the possibility of self-inflicted trauma been considered? In order to establish the diagnosis and to determine the appropriate treatment it will probably be necessary to excise a small portion of the affected area for histological examination: in particular Bowen's disease (intra-epidermal carcinoma) should be kept in mind. This is rare, but the description given, although not typical, is in keeping with this diagnosis.

Occupational Leucoderma

Q.—In March, 1941, it was reported from Washington that negro workers in tanneries noticed that the skin of their hands was turning white. This was said to be due to the presence of monobenzyl ether of hydroquinone, which was used to preserve the rubber gloves worn by the workers. I would be grateful for any concrete information about the above and any references to the literature.

A.—Monobenzyl ether of hydroquinone (quinol) is a powerful reducing agent, and as an anti-oxidant has been used in rubber compounding. It was the causative agent in an outbreak of occupational leucoderma among negroes working in a tannery in 1938; they wore a heavy gauntlet-type glove which had been treated with 0.2% of this anti-oxidant to preserve the rubber (Schwartz, Oliver, *et al.*, *Publ. Hlth. Rep., Wash.*, 1940, 55, 1111). White spots appeared on the areas of skin of the forearms and hands which were covered by the rubber gloves; there was itching with in some cases a mild dermatitis preceding the appearance of depigmentation, but there was no great discomfort or any disability. Hydroquinone monobenzyl ether is not a pigment bleach—that is, it does not decolorize melanin but simply prevents its formation. Repigmentation of the leucodermic areas followed cessation of the use of the anti-oxidant. The general health of the workers was not affected. Other references are: Schwartz, *Publ. Hlth. Bull., Wash.*, 1939, 249, 25; Schwartz, Tulipan, and Peck, *Occupational Diseases of the Skin*, 2nd ed., 1947, 153, 451.

Inheritance of Deaf-mutism

Q.—What are the chances of a second deaf-mute occurring in a family? The first child is a deaf-mute boy; the second is a normal boy. There is no history of deaf-mutism on the wife's side, but two cases are known on the husband's side—a male three generations back (a great-grand-uncle of the husband) and a female collateral (a direct descendant of the husband's great-grandmother). Can the chances be estimated with any degree of certainty?

A.—Hereditary deaf-mutism is due to a recessive gene. The absence (presumably) of any extraneous cause for the child's condition and the history of the defect in the father's family leave little doubt in this particular instance. The chance that any subsequent child will be similarly affected is 1 in 4. When the time comes for the children to marry there is no reason why the deaf-mute and the normal brother should not have children. Always provided that they do not marry blood relatives or women with a family history of deaf-mutism, the chance of the defect's appearing in the next generation is very small.

Sterilization of Rubber Gloves in Midwifery

Q.—Is it satisfactory bacteriologically to sterilize rubber gloves for use in midwifery by washing them on the hands in soap and water, drying, and then rubbing in "dettol" obstetric cream for five minutes? Will you discuss this in relation to intact gloves, patched gloves, or "holed" but unpatched gloves?

A.—The only really satisfactory procedure is to sterilize intact gloves by boiling or autoclaving and to apply them after the usual scrubbing of the hands. Except in emergency anything short of this is indefensible. If the wearing of damaged gloves is unavoidable they should be carefully patched, and if the patches are kept to the inside there is less risk of their becoming disturbed during operations. Procedures to be adopted in emergency will vary with the circumstances, but should be worked out with the ideal in mind, and with the knowledge that rinsing in antiseptic solutions or smearing with antiseptic cream, though better than nothing, is not very efficient. One of the difficulties in removing all bacteria by washing and scrubbing the bare hands is the surface irregularities. Provided care is taken where the gloves wrinkle at the wrist, this disadvantage is to some extent minimized by thorough washing of the gloved hands. If the gloves are patched, however, this advantage is lost and the procedure becomes less efficient. In any case the gloves should not be dried afterwards unless sterile towels are available. Punctured but unpatched gloves should not be used under any circumstances.

Undulant Fever

Q.—A veterinary surgeon working with S19 anti-abortion vaccine developed pustules on his forearm. Later he was clinically proved to have abortus fever. Shortly afterwards his wife developed the condition and aborted. (a) Is it reasonable to suppose that the husband's infection was caused by the vaccine? (b) Is it possible that he transmitted the condition to his wife? (c) Does it follow that her abortion was caused by the infection?

A.—(a) The S19 *Brucella abortus* vaccine is living but attenuated; whether the organisms contained in it could produce infection in man is not positively known. On the other hand, their reduced pathogenicity is likely to operate in man as well as in cattle, and a veterinary surgeon is in any case much more likely to have acquired the disease in the usual way from infected animals.

(b) Case-to-case transmission of undulant fever has not been observed; presumably it could occur, since the organism may be found in faeces and urine. Transmission by coitus is theoretically possible, but perhaps improbable, since coitus is unlikely in the acute stage, when the organism may be found in the urinary tract. The wife, of course, may also have acquired the disease from an infected animal or from milk. Further information about dates of onset and the existence of other possible sources of infection would be necessary in elucidating this interesting occurrence.

(c) *Br. abortus* can cause human abortion, but there can be no proof, short of demonstrating the organism in the uterus or placenta at the time, that it did so in any particular case.

Intractable Tinnitus

Q.—About seven months ago I developed tinnitus in my left ear; it is high-pitched and continuous, and is worse on waking. There is no pain, vertigo, or deafness, and no history of previous ear trouble. I am 50 years of age, highly strung, and a "worrier," but except for a mucoid nasal and post-nasal catarrh, particularly in the morning, I am healthy and free from any cardiovascular abnormality. Blood pressure 140/80 mm. Hg; red cell count 5.7 millions per c.mm.; haemoglobin 102%. Clinical examination of the ear shows no evidence of disease and the Eustachian tube is patent. X-ray films of the teeth and sinuses are negative, though there is an unerupted upper canine on the left side. The tinnitus is most distressing and I find it difficult to get to sleep. Bromides and phenobarbitone give me a disturbed rest and a depressing carry-over the next day. What is the cause of the condition and what is the immediate, and ultimate prognosis? Is there any treatment?

A.—Tinnitus is considered to be due to some irritation of the inner ear or auditory nerve, but in many cases the cause is not discovered, and in others the damage is irreversible, and so not amenable to treatment. All the usual causes seem to have been eliminated in this case. Lempert has described a small series of cases (*Arch. Otolaryng.*, Chicago, March, 1946) in which he divided the tympanic plexus of nerves. In most cases the tinnitus was alleviated, but the series was too small for any convincing conclusions to be drawn. Acid, hydrobrom. dil. or ammon. brom. are the most generally useful sedatives. In the present case the tinnitus will probably be permanent but become more bearable as time goes on.

NOTES AND COMMENTS

Food Allergy.—Mr. ERIC C. WOOD, Ph.D. (London, W.), writes: May I add one further comment on the subject of sensitivity to egg in a child (Nov. 29, 1947, p. 896)? It is far more likely if a child is genuinely sensitive to egg that the allergy is to egg white rather than egg yolk. Marriott, W. M., and Jeans, P. C., in their book *Infant Nutrition*, London (3rd edition, 1942, pp. 224 and 225), say: "A fear that formerly existed that the effect of egg in early infancy might lead to the development of sensitivity to egg protein seems unfounded in the light of extended clinical experience in instances in which only the yolk has been fed. It is desirable that the egg be cooked." While they suggest that egg yolk may be added to the diet of the infant at as early an age as three months, they state that whole egg may be given toward the end of the first year. The chief reason it is not commonly given earlier is the possibility

that sensitivity to protein of egg white may develop as a result of the feeding. . . . At whatever age the feeding of egg white is started, it should be given cautiously and in small amounts at first." The point is of importance, since egg yolk is a most important food providing valuable quantities of many essential nutrients, not the least important of which is iron. Moreover, most babies find egg yolk extremely palatable. It would be a great pity if babies were deprived of a toothsome delicacy which is also an excellent food because they are allergic to egg albumen.

Ringworm of Scalp.—Col. W. H. CRICHTON, C.I.E., I.M.S. (ret.), writes from Sittingbourne, Kent, with reference to Dr. J. T. Duncan's letter (Nov. 29, 1947, p. 896): The causative fungus in all the cases I had in North Devon was reported by the Devon County Laboratory to be the *Microsporum felinum*. I refer to cases which occurred between February and May, 1947.

Superfluous Hair.—J. M. writes: The problem of superfluous hair becomes of the utmost importance to some women. Personally, I greeted the original *B.M.J.* answer (Nov. 15, p. 805) with approval as giving sensible and practical advice. To my mind it is quite impractical to advise electrolysis as a routine measure and usually unnecessary, except in those cases where there are a small number of exceedingly stiff hairs. The commonest problem arises with a woman, say in the early thirties, who feels that she has become unsightly through a generalized growth of hair. Clearly the trouble will be progressive, and to embark on electrolysis would be endlessly tedious and costly. Her choice of methods is either depilatory wax or an occasional shave. The advantage that wax offers is that since the hair is pulled out from the follicle the new growth of hair, when after several days it comes through, is soft and quite unlike the cut-off, bristly quality of a shaved hair. Most women who begin with depilatory wax in the twenties or thirties do not ever require to use it more than once in several days; the process takes some five or ten minutes, and the results are frequently perfect. On the other hand, shaving may sometimes become a daily necessity for a fastidious woman; but even so it is always wise to assure her that her growth will never become that of the average masculine skin. To my mind it is the way in which advice is administered which is the important factor; many middle-aged women feel that they are the only sufferers, and experience intense humiliation. They are greatly relieved to have it pointed out that their friends with immaculate skin have probably been using wax for a decade and that it is high time that they themselves followed suit. The really difficult part of this procedure is relieving the patient of her humiliation and her masochistic impression that she must expect to endure and suffer!

Constipation in an Infant.—Dr. ANN MOWER WHITE (London, W.) writes: I have only just seen the question and answer (Nov. 29, 1947, p. 896) about "Constipation in an Infant," and I am rather surprised at the reply. In the first place the questioner does not state whether the 4-month-old male infant is breast- or artificially fed. In a breast-fed baby an interval of seven days between bowel actions is not at all uncommon, and may be called "false" constipation in contradistinction to "true" constipation, when the stools are infrequent and hard. For "false" constipation no treatment is required beyond reassuring the mother that her milk is suiting her baby so well that there is little rubbish to pass out. If more active advice is needed, she should be told to give the baby more free kicking exercise with napkin removed and to give more water to drink in the daily routine. In an artificially fed baby "true" constipation is a more likely occurrence. The psychological trauma likely to be incurred by the daily anal insertion of a soap stick or a vaselined glass rod (as advised in the answer to the question) is a remedy fraught with too grave a risk to allow any mother to use it. More sugar added to the feeds, more water during the day, and a mild laxative such as milk of magnesia would be the more harmless procedure.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Alitext*, *Westcott*, London. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* and unless the contrary be stated.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JANUARY 3 1948

SUPERANNUATION SCHEME FOR PRACTITIONERS

BY

HORACE KEAST, D.P.A.

Establishment Officer, Cornwall County Council

Under the provisions of the National Health Service Act, 1946, the Minister of Health is empowered to make regulations for the setting up of a comprehensive superannuation scheme for officers of the various bodies established under that Act, including medical practitioners providing general medical services. These regulations, which constitute an elaborate superannuation code, have recently been issued and are entitled the National Health Service (Superannuation) Regulations, 1947. The staffs of Regional Hospital Boards and Management Committees, as well as those of Executive Councils, are covered by these regulations, and there are special provisions for the granting of benefits on a contributory basis to practitioners rendering general medical services under the Act—i.e., medical practitioners on the lists of Executive Councils. The regulations consist of 88 pages of statutory phraseology, and a brief outline of the salient features affecting such practitioners may therefore be helpful.

The benefits provided for medical practitioners employed by Executive Councils include retirement pensions plus lump-sum capital retiring allowances, short-service gratuities in special cases, widows' pensions, and death gratuities. The granting of a pension to the widow of such a practitioner, irrespective of whether he dies before or after his own retirement, is a particularly valuable part of the scheme.

The superannuation allowance of a medical practitioner so far as his employment with an Executive Council is concerned will be based on the formula: "in respect of each year of contributing service as a practitioner, $1\frac{1}{2}\%$ of his remuneration for that year." That is to say, the pension will be calculated by taking $1\frac{1}{2}\%$ of the net remuneration of the practitioner payable by the Executive Council for each year of his contributing service, and the aggregate of these amounts will form an annual allowance, payable as from the first day of retirement. In addition to this annual pension there will also be a lump-sum capital payment, payable on retirement. In the case of a female practitioner or an unmarried male practitioner on the lists of an Executive Council, this capital sum will be based on the formula: "in respect of each year of contributing service as a practitioner, $4\frac{1}{2}\%$ of his remuneration for that year." The aggregate sum will be computed in the same manner as the annual pension rate.

In the case of a married practitioner on the lists of an Executive Council, in respect of whose service a widow's pension may become payable, however, the capital sum will be based on $1\frac{1}{2}\%$ of remuneration instead of $4\frac{1}{2}\%$. Generally, the amount of a widow's pension will be one-third of the amount earned by the service and remuneration of her husband in his Executive-Council employment up to the date of his death, subject, however, to an adjustment if the age of the widow is less than that of her husband. There will also be a death gratuity payable to the widow, calculated by reference to $1\frac{1}{2}\%$ of the remuneration for each year of contributing service of the practitioner up to the date of death. Widows' pensions and gratuities are not payable when the marriage takes place after the husband attains pensionable age, and a widow in receipt of a pension gives up that allowance on remarriage. In

the case of an unmarried practitioner a death gratuity, based on $4\frac{1}{2}\%$ of the remuneration of each year of contributing service, may be payable to his legal personal representatives. The regulations also contain provisions for injury allowances where the officer is permanently incapacitated by injury suffered in the course of duty, short-service gratuities for those who have completed more than five but less than ten years' service, and special provisions for grants to widows whose husbands cease their employment with an Executive Council after completing five years' service and die within twelve months after so ceasing.

Pensionable Age

The normal pensionable age of a medical practitioner to retire from the employment of an Executive Council shall be sixty-five years or such later age as the Minister of Health may allow in any particular case. In the event of such a practitioner having more than forty years' contributing service the pension shall be calculated by reference to "the last forty years' contributing service." The earliest age that a contributor can retire, however, is 60 years, provided that he has by that age completed ten years' service. If, however, a contributor has completed ten years' contributing service and is incapable of discharging efficiently the duties of his employment by reason of permanent ill-health or infirmity of mind or body, he thereupon becomes entitled to the benefits earned up to that date.

So far as medical practitioners on the lists of Executive Councils are concerned the word "remuneration" in these regulations has a prescribed meaning. The definition is "all payments made to the practitioners in respect of general medical services provided by him, and of pharmaceutical services provided by him, less such sum on account of practice expenses as may be appropriate in accordance with a formula laid down by the Minister for the purpose, and less the remuneration approved by the Minister of any assistant practitioner in his employment." In cases of partnerships the remuneration of the practitioners is calculated by reference to their respective shares in the partnership agreement. The regulations granting pension rights of all types apply, of course, to assistant practitioners in practices rendering general medical service under the Act, save that their remuneration may mean either their whole salary and emoluments or such part thereof as the Minister may approve.

Where a practitioner has also been employed in any of the public services, as, for example, part-time medical officer to a local authority, there are regulations dealing with such previous public service. So far as medical officers who have no such previous public service, and who are employed by no other bodies than executive councils, are concerned, however, service will generally be confined to contributing service.

The contributions which a practitioner employed by an Executive Council will have to pay to qualify for the foregoing range of benefits will be 6% of his remuneration, as calculated by the formula already quoted. In addition to this contribution the Executive Council, acting as the employing authority, must pay to the central funds an additional 8% of the remuneration of each practitioner. While the employing authority of practitioners on the lists of Executive Councils will be those Councils, the practitioner himself is regarded as the employing authority of any assistant practitioner in his employ. The contributions deducted from the assistant's salary, together with the employing practitioner's 8% contribution, must be sent to the Executive Council.

HEARD AT HEADQUARTERS

The National Insurance Act, 1946, the central statute in the social security legislation, will come into operation on July 5, 1948. Every person in the country between school-leaving age and pensionable age will be compulsory contributors under that scheme, save that wives will be insured by virtue of their husbands' contributions, and there will be differential contribution rates for males and females in the three categories of employed, self-employed, and non-employed persons. All medical practitioners, including those employed by Executive Councils, will be compulsory contributors to this State scheme, and the benefits will include a personal pension of 26s. a week at age 65 or £2 2s. a week for a married couple. There are also provisions for pensions for widows. There can be no exceptions to this State scheme; every person, irrespective of income levels, must be compulsorily insured.

It has been enacted, however, that contributors to such schemes as the Health Service Superannuation Scheme shall have a small reduction, generally £3 0s. 8d. a year, in their contributions to such schemes. This will result in an appropriate reduction in the eventual superannuation allowance payable under the Health Service Superannuation Scheme. The amount of this reduction depends on the age of the person concerned at the commencement of the scheme and the number of years' service before retirement, but in no case will it exceed 26s. a week, which is the minimum pension the person concerned will be receiving from the State scheme on retirement after attaining the pensionable age of 65. Certain classes of officers who are already subject to the superannuation enactments relating to local-authority or public-service employment and practitioners who enter Executive Council lists on the appointed day will be exempt from this modification, thus enabling them to pay full contributions to both pension schemes and hence receive both pensions in full, unless they individually elect to come under the modified scheme within a prescribed time limit. Medical practitioners to whom this right of option applies will be informed by the appropriate authority in due course.

It will be appreciated that the foregoing is only an outline of the main features of the National Health Service Superannuation Scheme; so far as it affects practitioners on the lists of Executive Councils. It is not possible within the limits of a single article to deal with all the complicated qualifications which affect special circumstances and eventualities, such as the preservation of rights during any period of national service or when a practitioner receives no remuneration in consequence of an extensive period of sick leave. There are a large number of special provisions dealing with particular conditions. It is anticipated that explanatory booklets and leaflets will eventually be issued by the Ministry, and these should be studied in detail by practitioners to whom they apply.

Finally, there is one regulation which may be of exceptional importance to certain practitioners on the lists of Executive Councils. It states that, "where any person holding a contract or policy of insurance with any of the life assurance companies becomes a practitioner on the appointed day, then, if he so requests the Executive Council in writing within three months after the appointed day, the Minister may agree that the practitioner shall not, so long as he continues to be a practitioner, become subject to any provisions of these regulations except this provision, and in that event the Minister shall, subject to such terms and conditions as the Minister may determine, pay to him as a contribution towards the maintenance of the contract or policy an amount equal to 8% of his remuneration as a practitioner as defined in paragraph (2) of this regulation." That definition of remuneration has already been explained earlier in this article. If this option is exercised, the Minister's contribution towards the premium of the policy or contract takes the place of any of the benefits provided by the Health Service Superannuation Scheme.

The Battle of the Documents

The Council has given careful consideration to the form of question to be used in the plebiscite and to the size of the majority that would justify action. These will come forward as recommendations to the Special Representative Meeting on Jan. 8, and forms in the plebiscite will be issued at the end of that month.

Unhappy Endings

Unhappy endings have attended the Four-Power talks at Lancaster House and equally the Negotiating Committee's talks with the Minister of Health in Whitehall, but there is one difference between the two breakdowns which is to the disadvantage of the doctors. In the case of the Four-Power talks the Press was present every day, and the public was able to judge the issue as the proceedings developed, so that not only, was it prepared for the final calamity but it was able to judge where the responsibility lay. The talks with the medical profession, on the other hand, were conducted in secrecy, and even when they ended—the Negotiating Committee well knowing that the Minister was not going to concede an inch—a further silence was imposed upon them for sixteen days until the Minister had his very clever last word. The public, perhaps unaware even that talks have been proceeding, and knowing nothing of the stone wall against which the Negotiating Committee have been beating their heads, may well feel bewildered and unable to say whether an obstinate Minister or a "reactionary" profession is the more to blame.

Months Ahead

The next three months bid fair to being the most strenuous time since the dawn of medical politics. Much planning and executive work are involved in the arrangements of a plebiscite, in the organization of meetings near and far, and in the guidance of inquirers, all in addition to the normal turning of Association machinery. Many Divisions of course have their own speakers, but a request from any Division for a speaker from Headquarters, whether an officer of the Association or a member of the Council, will be met wherever possible.

Roping in Volunteers

The L.C.C. seems to be genuinely anxious to ensure the continuance of the many voluntary health organizations in which the metropolis abounds. The chairman of the Hospital and Medical Services Committee told his Press conference the other day that all voluntary organizations at present doing useful work are being invited to continue that work under the new auspices, subject to the Council having the power to look at it from time to time and having also a small representation on the governing body. Mr. Stamp declared that a great measure of good will had already been shown on the part of these voluntary bodies, though a few of them have thrown in their hand and asked the Council to undertake the provision which hitherto they have been making. Home nursing is a field of service not undertaken up to now either by the L.C.C. or by the metropolitan boroughs whose health services are being taken over; it has been carried on solely by voluntary institutions, gathered under the general umbrella of the Central Council for District Nursing, and the L.C.C. intends to act through that excellent agency.

The Subacute Hospital Problem

In a document presented at the last meeting of the Hospital Committee by one of its members, Dr. W. S. Macdonald, of Leeds, with a supplementary note by Dr. H. Joules, Dr. Macdonald suggested that some form of central bureau may soon be essential in each hospital district. Not only must there be a limitation of admissions, especially in subacute cases, but methods will have to be thought out for expediting discharge to convalescent homes and hostels as well as to normal domestic surroundings. Such bureaux could play a very real part in ensuring the closest co-operation between the hospital, the practitioner, and the general public on behalf of the particular patient.

Dr. Walter Atten, of Bournemouth, who has been chairman of the health committee of the local county borough council for nearly 20 years, has been elected Vice-chairman of the Bournemouth Literary Council.

Social Medicine No New Thing

A very interesting description of the many activities of the Institute of Social Medicine at Oxford was given by Prof. I. A. Ryle, who is at its head, to the Medical Society of London the other evening, but in the subsequent discussion some feeling was expressed that social medicine might become too academic. One or two medical men said that during their student days or just after qualification they learned their social medicine—although it was not called by that name—on the district, perhaps in Bermondsey, in the neighbourhood of Guy's, or in Whitechapel, in the neighbourhood of the London, or in

Lisson Grove, in the neighbourhood of St. Mary's, where they had gone into the homes of the people and had learned things of great value to them in their subsequent career, whether in consultant or general practice. One of the early exponents of social medicine was Abercrombie, who set up his public dispensary in Edinburgh, where he and his students obtained an intimate knowledge of the moral and physical condition of the poor. There was also Lettsom, whose general dispensary in Aldersgate Street was the first of its kind in London. One general practitioner remarked at the meeting that he had been practising social medicine for a lifetime without being aware of it.

MEDICAL WAR RELIEF FUND: SEVENTH ANNUAL REPORT

1. This report covers the period of twelve months from Sept. 1, 1946, to Aug. 31, 1947. Appended to the report is the audited statement of accounts of the Fund for the same period.

2. The number of awards made during the year was 49. Ten of these were loans and the remainder gifts. In addition a loan awarded during a previous year was converted into a gift. The total amount of the awards made during the year is approximately £11,000, and the total of all awards since the inauguration of the Fund is nearly £62,000. The administrative expenses incurred since the Fund was established seven years ago amount only to £1,042.

3. As in the previous year, most of the applications came from ex-Service medical officers who needed temporary assistance on their return to civilian practice. Their difficulties were due in some cases to the bombing of their professional premises during the war, and in others to ill-health or disability resulting from military service.

4. The Fund has continued to make suitable provision for widows and children of doctors who lost their lives in the war. It gladly voted a substantial sum to defray the travelling expenses to and from Switzerland of three parties of children of doctors killed or incapacitated during war service. The children were thus enabled to benefit from a rehabilitation scheme generously promoted by the Swiss medical profession.

5. It is with deep regret that the Committee records the death

of one of its members, Sir Arnold Lawson, who held the office of Vice-Chairman of the Distribution Subcommittee. His whole-hearted interest in the work and unfailing sympathy and judgment were of the greatest value.

6. The Committee has accepted with regret the resignation of Dr. J. W. Bone from the office of Honorary Treasurer, in which he has rendered notable service to the Fund since its inauguration. The Committee records with gratitude its indebtedness to him. It has appointed Dr. C. L. Batteson to succeed him as Honorary Treasurer.

7. The Committee wishes to express thanks to those subscribers who have continued their generous support of the Fund during the past year. As has already been announced, it now considers that further contributions are unnecessary. Thanks are due also to the British Medical Association for its assistance in providing accommodation for meetings and in other ways; and once again the Committee records its deep appreciation of the indispensable co-operation received from the Royal Medical Benevolent Fund and the ever-ready help and interest of Mr. E. C. Pennecfather, whose experience in the work of the R.M.B.F. has been of the greatest service. Finally, the Committee acknowledges with gratitude its continued indebtedness to Messrs. Price, Waterhouse and Co., who have again generously given their services as Honorary Auditors.

H. GUY DAIN,
Chairman.

STATEMENT OF ACCOUNTS FOR THE TWELVE MONTHS ENDED AUG. 31, 1947

	£	s.	d.	£	s.	d.
To Balance Brought Forward:						
£7,000 3% Savings Bonds, 1955/65 ..	7,000	0	0

Chartered Accountants,
Honorary Auditors.

Nov. 14, 1947.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

County Borough Councils.—Barnsley, Gateshead.
Metropolitan Borough Councils.—Fulham, Hackney, Poplar.
Non-County Borough Councils.—Dartford, Leyton, Radcliffe (limited to future appointments), Tottenham, WallSEND.
Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Stanley (Co. Durham), Tyldesley.
Scottish Burghs.—Motherwell and Wishaw.

RELEASE OF MEDICAL OFFICERS FROM
H.M. FORCES

The Central Medical War Committee has been notified of the following arrangements for the release in Class A of medical officers during the first quarter of 1948:

Royal Navy			
January	Group 66
February	Groups 67 and 68
March	Groups 69, 70, 71, 72, and 73
Royal Army Medical Corps			
General Duty Officers			
January	Group 64
February	Group 65
March	Group 66
Physicians, Surgeons, Gynaecologists			
January	Group 59
February	Group 60
March	Group 61
Other Specialists			
January	Group 57
February	Group 58
March	Group 59
Royal Air Force			
January	Groups 65, 66, and 67
February	No release
March	Group 68

Association Notices

NATIONAL ASSISTANCE BILL

As was reported in the *Supplement* of Dec. 20, 1947 (p. 164), the Special Committee which is considering the National Assistance Bill requested that the Minister of Health receive a deputation to hear the Committee's views on the question of compensation for Public Assistance District Medical Officers who will suffer loss of emoluments attributable to the passing of the Act. The Ministry has stated in reply that no useful purpose would be served by such a meeting on the grounds that the Government's views on the matter are quite clear—namely, that there should be no compensation in the case of part-time officers.

Arrangements are now in hand for discussions between members of the Committee and the Parliamentary Medical Group. It is expected that a meeting with the Group will take place at the House of Commons on Jan. 27.

SCHOLARSHIPS IN AID OF SCIENTIFIC RESEARCH

The Council of the British Medical Association is prepared to receive applications for Research Scholarships as follows: An Ernest Hart Memorial Scholarship of the value of £200 per annum, a Walter Dixon Scholarship of the value of £200 per annum, and four Research Scholarships each of the value of £150 per annum. These scholarships are given to candidates whom the Science Committee of the Association recommends as qualified to undertake research in any subject (including State medicine) relating to the causation, prevention, or treatment of disease. Preference

will be given, other things being equal, to members of the medical profession.

Each scholarship is tenable for one year starting on Oct. 1, 1948. The scholar may be reappointed for not more than two additional terms. A scholar is not necessarily required to devote the whole of his or her time to the work of research but may hold an appointment at a university, medical school, or hospital, provided the duties of such an appointment do not interfere with his or her work as a scholar.

In addition, applications are invited for the first award of the Insole Scholarship of the value of £250 for research into the causes and cure of venereal disease.

Conditions of Award: Applications

Applications for scholarships must be made not later than Friday, April 30, 1948, on the prescribed form, a copy of which will be supplied on application to the Secretary of the Association, B.M.A. House, Tavistock Square, London, W.C.1. Applicants will be required to furnish the names of three referees who are competent to speak of their capacity for the research contemplated.

Diary of Central Meetings

JANUARY

8 Thurs. Special Representative Meeting, 11 a.m.
 21 Wed. Council, 10 a.m.

Branch and Division Meetings to be Held

EAST HERTS DIVISION.—At County Hall, Hertford, Sunday, Jan. 4, 2.30 p.m. Dr. E. A. Gregg: The National Health Act. All medical practitioners in the area of the Division are invited.

LEEDS DIVISION.—At Philosophical Hall, City Museum, Park Row, Leeds, Sunday, Jan. 4, 2 p.m. Special general meeting. Discussion: (1) The Negotiating Committee's Statement to the Minister of Health. (2) The Minister of Health's Reply. All medical practitioners in the area of the Division are invited.

METROPOLITAN COUNTIES BRANCH.—At B.M.A. House, Tavistock Square, London, W.C., Tuesday, Jan. 6, 5 p.m. Lecture by Dr. C. Keith Simpson: Crime and the Doctor. All senior students and newly qualified practitioners in the London area are invited to attend.

SOUTHAMPTON DIVISION.—At Royal South Hants and Southampton Hospital, Monday, Jan. 5, 8.30 p.m. Dr. Charles Hill (Secretary, B.M.A.) will address an open meeting of the profession. All medical practitioners in the area of the Southern Branch are invited to attend.

STOCKTON DIVISION.—At Stockton and Thornaby Hospital, Bowesfield Lane, Stockton-on-Tees, Monday, Jan. 5, 8.30 p.m. Address by Mr. W. Grant Waugh.

WESTMINSTER AND HOLBORN DIVISION.—At City Hall, Charing Cross Road, W.C., Thursday, Jan. 8, 8 p.m. Special meeting 8.15 p.m. Meeting of all medical practitioners in the area of the Division to discuss present position of the negotiations concerning the National Health Service Regulations.

WINCHESTER DIVISION.—At Nurses' Home, Royal Hants County, Sunday, Jan. 4, 11 a.m. Discussion: The National Health Service Act, 1946. (i) The Minister of Health's Statement to the Minister of Health. (ii) The Minister of Health's Reply.

Meetings of Branches and Divisions

HASTINGS DIVISION

Addressing a meeting of the Hastings Division on Dec. 2 on "The Catarrhal Child," Dr. E. A. Wood read case notes to illustrate chronic or recurrent bronchitis, often punctuated by attacks of pulmonary consolidation or atelectasis—of which, with the sequelae bronchiectasis, emphysema, and chest deformities, he showed x-ray photographs. Prevention was by adequate convalescence from measles, whooping-cough, or pneumonia, and care of upper respiratory infection. Treatment was based on pathology. Loss of cilia and bronchial ulceration demanded thin sputum (achieved by iodine and alkali), which would flow with postural drainage. Atelectasis, emphysema, asthma, and chest deformities required breathing exercises. Correct posture for drainage of bronchiectasis was ensured by bronchography. Lobectomy might cure. Whooping-cough vaccine should be given to susceptibles; and contacts who had not had measles should be given convalescent serum.

SALISBURY DIVISION

The Salisbury Division held one of its most successful meetings on Nov. 26 at Salisbury. It had been decided to invite the members of the legal profession, and 71 members and visitors dined together including about 20 lawyers. Dr. A. D. H. Simpson was in the chair. After dinner Mr. W. Bentley Purchase delivered a B.M.A. lecture on "Some Medico-legal Experiences of a London Coroner." A vote of thanks was proposed by Mr. A. Duff and carried with acclamation.

Correction.—Dr. Thomas Scott was erroneously described as Mr. Thomas Scott in the list of members of the Scottish Regional Hospital Boards printed in the *Supplement* of Nov. 8 (p. 111).

ANAEMIA ASSOCIATED WITH TRAUMA AND SEPSIS*

BY

JANET VAUGHAN, D.M., F.R.C.P.

Department of Pharmacology, Oxford

Since the Goulstonian Lecturer in 1932 took as his subject the "pathology and treatment of anaemia" great advances have been made in our understanding of the aetiology and treatment of many blood diseases. There are, however, two extremely common anaemias the cause of which remains obscure and the treatment unsatisfactory—namely, the anaemia found in association with infection and the anaemia found in association with trauma.

My reasons for considering these two conditions together are: (1) The morphological character of the anaemia is the same and there are striking similarities in the metabolic findings. (2) There is no effective treatment of the anaemia beyond supplying already matured red cells in the form of transfusions while awaiting improvement in the underlying infection or healing of the injured tissues. (3) The available evidence suggests that in both conditions the synthesis of haemoglobin is in some way at fault and that this failure of haemoglobin synthesis is responsible for the anaemia.

In discussing the anaemia both of trauma and of infection it must be remembered that in recent years the picture has almost invariably been complicated by treatment with the sulphonamides, which may themselves affect haemopoiesis (Rimington, 1939). Further, trauma is likely to be complicated by infection, and in some instances the reverse may occur—for example, the presence of osteomyelitis or empyema may necessitate operative intervention. However, relatively simple cases of each have been recorded (Saifi and Vaughan, 1944; Howard, 1945) in which anaemia is still found.

Anaemia of Sepsis: Morphological Characteristics

In considering the morphological character of anaemia associated with sepsis it is probably important to differentiate between acute and severe infections and more chronic infections, though it is difficult to know how best to make the distinction. In a previous study (Saifi and Vaughan, 1944) the presence of an infection of longer than three months was regarded as chronic, while anything less than three months was regarded as acute. It might be wiser to make the distinction depend rather on the virulence and nature of the infectious process than on its duration.

Anaemia Associated with Virulent Infection

In certain fulminating infections, such as with *Clostridium welchii*, the anaemia is certainly haemolytic and often megalocytic. Other scattered examples of proved haemolytic anaemia associated with severe infection characterized

by a high colour index and sometimes increased red-cell fragility have been described (Brown *et al.*, 1944; Mollison, 1947). Such cases, however, occur as interesting rarities meriting special description. Mollison (1947) reported two unusual cases of hyperchromic anaemia and sepsis—one associated with advanced bilateral tuberculosis, the other with acute osteomyelitis. In both the anaemia was severe—in one there was increased red-cell fragility, in the other it was not recorded. A few similar cases associated with severe sepsis in burns have been described (Brown *et al.*, 1944). Rare cases of hyperchromic megalocytic anaemia unassociated with lesions of the gastro-intestinal tract have also been reported in tertiary syphilis (Tauber and Goldman, 1935).

Blackfan and Diamond (1944) observed 15 infants between the ages of 4 and 16 months in whom a severe megalocytic anaemia developed in association with acute infection and was corrected by the parenteral administration of liver extract. In only one was a prolonged course of liver therapy needed. The remaining children recovered completely after a single course of treatment. The anaemia was associated with a temporary complete achlorhydria. Unfortunately no details are given. Since the anaemia responded to treatment apparently in the presence of infection, it seems possible that it was primary in origin, though even in primary anaemias infection often has an inhibiting effect on the action of haemopoietic factors. Zuelzer and Ogden (1946) reported 26 presumably similar cases in infants 2 to 11 months old in which the bone marrow resembled that of pernicious anaemia—megaloblasts and giant metamyelocytes being present in large numbers. The anaemia was not always megalocytic, but was often associated with leucopenia, neutropenia, and thrombocytopenia. Such cases responded to folic acid or liver extract. It is, however, not altogether clear whether the anaemia followed the infection, or vice versa.

The anaemia associated with *Brucella* infections also merits special mention. It has been recorded by Calder *et al.* (1939) as being macrocytic and hyperchromic, and by Harris (1941) as being sometimes like pernicious anaemia. I have seen it on at least four occasions with a high colour index and young red and white cells in the peripheral blood—in fact, a leuco-erythroblastic type of anaemia, which caused considerable confusion in diagnosis. Characteristically it is of the normocytic hypochromic type (Cartwright *et al.*, 1946a).

Anaemia Associated with Chronic Infections

The anaemia associated with chronic or non-fulminating infections is normocytic and normochromic in the majority of cases, though it may become somewhat microcytic and

*The Bradshaw Lecture given at the Royal College of Physicians of London on Nov. 6, 1947.

hypochromic if the infection is of long standing. In 24 cases of infective endocarditis Pepper (1927) recorded a hypochromic type of anaemia associated with both a *Streptococcus viridans* and a haemolytic streptococcal infection. Horder (1926) alone claimed to have found a high colour index in infective endocarditis, but he gave no numerical data. In tertiary syphilis moderate hypochromic anaemia may occur, particularly in untreated cases. It is less pronounced than in the primary and secondary stages (Rosahn and Pearce, 1934; Tauber and Goldman, 1935).

In rheumatic fever the cell size, the mean corpuscular haemoglobin, and the mean corpuscular haemoglobin concentration in one large series varied from low to normal values (Hubbard and McKee, 1939). In chronic rheumatic conditions, especially in women, a hypochromic type of anaemia is common, and is often but not necessarily associated with achlorhydria (Collins, 1935). The severer grades are found in cases of atrophic rheumatoid or infective arthritis.

Josephs (1936) stated that in infants the anaemia tends to be hypochromic and that extreme hypochromia is rare. Blackfan and Diamond (1944) also described a microcytic hypochromic anaemia in infants and a mixed type showing microcytosis and macrocytosis, the latter responding to liver and to iron after recovery from the infectious process, suggesting that there is a deficiency of both.

Rasmussen (1936), reviewing the blood picture in 460 patients with pulmonary tuberculosis, noted a hypochromic type of anaemia in 12% of cases. In 34 non-febrile cases the anaemia responded to liver therapy. In 13 there was widespread tuberculosis involving the intestinal canal, presumably therefore interfering with intestinal absorption. In 10 cases other forms of infection, such as with haemolytic streptococci, were present. Braverman (1938, 1942), from a review both of his own cases and of the literature, concluded that the anaemia in tuberculosis, if present, is usually mild, most commonly hypochromic and microcytic, but sometimes normochromic and normocytic. He found such anaemias in 46% of a series of 509 patients.

Saifi and Vaughan (1944) in 34 cases and Cartwright *et al.* (1946a) in 16 cases of anaemia associated with such infections as osteomyelitis, empyema, infective endocarditis, chronic nephritis, and pneumonia failed to find a macrocytic type of anaemia. The anaemia was mild, normocytic, and normochromic, or slightly microcytic and hypochromic. In a series of 464 cases Wintrobe (1934) found no case of a megalocytic type of anaemia, and hypochromia was observed only in association with blood loss or nutritional deficiency. The anaemia was normocytic or slightly microcytic. Under experimental conditions in animals an anaemia with exactly the same morphological features is produced by the injection of bacteria or by the production of a sterile abscess by turpentine (Robschey-Robbins and Whipple, 1936; Cartwright *et al.*, 1946b). The injection of bacterial toxins alone does not cause anaemia, suggesting, as will be discussed later, that the essential factor in infections responsible for the anaemia is inflammatory tissue reaction.

Bone Marrow.—The accounts of bone-marrow findings in anaemia associated with sepsis are largely unsatisfactory, as only very partial examination of the skeleton is usually made. In both acute and chronic infections in which we examined the long bones from arm and leg and wedges from sternum, vertebral column, and pelvis we found active marrow often in excess of normal. All patients showed considerable erythroblastic activity though there was excessive leucopoiesis. In some instances there was myeloid activity of the spleen (Saifi and Vaughan, 1944).

Metabolic Characteristics of the Anaemia of Sepsis

In recent years there has been an increasing amount of data concerning what may be described as the metabolic characteristics of the common anaemia found in association with sepsis.

Serum bilirubin is within normal limits (Vaughan and Saifi, 1939; Saifi and Vaughan, 1944; Cartwright *et al.*, 1946a).

Plasma iron is low (Heilmeyer and Plötner, 1937; Schafer, 1940; Hirvonen, 1941; Bröchner-Mortensen and Stein, 1942; Cartwright *et al.*, 1946a). The fall in plasma iron immediately follows the infectious process even in those cases in which no anaemia develops. The normal range for humans is 120 ± 30 $\mu\text{g. per 100 ml.}$, while in 16 cases of anaemia associated with infections recorded by Cartwright *et al.* (1946a) the values ranged from 15 to 40 $\mu\text{g.}$ The hypoferracmia persists so long as the infection continues, and returns to normal more slowly than the haemoglobin or red cells.

Serum Copper.—On the other hand the serum copper is raised. The normal range determined by Cartwright *et al.* (1946a) was 116 ± 20 $\mu\text{g. per 100 ml.}$ The value in the 16 patients already mentioned was 200–262 $\mu\text{g.}$ with two exceptions.

Erythrocyte Protoporphyrin.—This porphyrin—protoporphyrin type III, from which haematin is formed by conjunction with iron—was with one exception increased in 11 cases studied by Cartwright *et al.* (1946a). The normal range is 20–50 $\mu\text{g. per 100 ml. of red cells.}$ In the patients studied it was increased two to fourteen times above normal, reaching a maximum in one instance of 634 $\mu\text{g. per 100 ml. of red cells.}$ This rise occurs slowly during the development of anaemia and returns slowly to normal after recovery.

Urinary and Faecal Coproporphyrin.—Vaughan and Saifi (1939) recorded an increase of both coproporphyrin I and III in the urine: an average of 427.1 $\mu\text{g. daily}$ was found in one patient; in another there was an increase of coproporphyrin I with only a trace of III; in a third there was an increase in urinary porphyrin but not enough for identification. The faecal porphyrin consisted of a chloroform-soluble fraction (protoporphyrin deuteroporphyrin) and an insoluble coproporphyrin fraction containing coproporphyrin III. Cartwright *et al.* (1946a) also reported an increase in urinary coproporphyrin but did not differentiate the type. A similar increase in coproporphyrin III excreted in infections in the urine has been noted by Rimington and Hemmings (1938), by Curphey and Solomon (1938), and by Watson and Larson (1947), particularly in acute poliomyelitis. The last-named workers recorded an increase of coproporphyrin I in certain infections, particularly infectious hepatitis.

Faecal Urobilinogen.—There are relatively few data available on urobilinogen excretion in anaemia associated with infection. Eppinger and Charnas (1913) noted a normal figure in a patient with anaemia and pulmonary tuberculosis. Bauman (1921), using a rather unsatisfactory method of estimating, recorded normal figures in two cases of infectious endocarditis. Weiss (1930) noted a patient with tuberculous glands who excreted 56 $\mu\text{g. of urobilinogen daily}$ and three cases of pulmonary tuberculosis with figures ranging from 54 to 132 $\mu\text{g. daily.}$ Paschkis (1933) recorded a case of infective endocarditis with a daily excretion of 228 $\mu\text{g.,}$ and Heilmeyer and Plötner (1937) quoted a case of rheumatic polyarthritis with an absolute excretion of 77 $\mu\text{g. daily.}$ Watson (1938) recorded a patient with chronic infectious arthritis in whom the excretion was 60 $\mu\text{g. daily.}$ Our own series of eight cases, the largest available, showed no increase above normal in seven patients and in the eighth an increase so slight as to be insignificant, the upper figure for normal in men being taken as 280 $\mu\text{g.}$ (Vaughan and Saifi, 1939). The same results were obtained when excretion was related to the total circulating mass of haemoglobin rather than expressed in absolute amounts.

Urobilinogen in Urine.—We (Vaughan and Saifi, 1939) observed no increase in urinary urobilinogen, but increases have been noted by other workers (Harris, 1927; Weiss, 1930; Watson, 1938; Curphey and Solomon, 1938; Hubbard and McKee, 1939).

Plasma Proteins.—In the series of cases investigated by Cartwright *et al.* (1946a) the plasma proteins were within the

normal range, varying from 5.9 to 7.4 g.% and in those patients examined the relative proportions of albumin and globulin were not disturbed. Peters and van Slyke (1931) reported, however, that in chronic infection the plasma albumin concentration may be low, and one or two instances of low total protein are recorded in association with rheumatic fever and tuberculosis by Bing (1946) in his study of hypoproteinaemia. Grossman *et al.* (1945) in a series of patients with known negative nitrogen balance found normal levels for both total protein and plasma albumin. Wintrobe *et al.* (1947b) also stated, without giving evidence, that the albumin may be low.

Nitrogen Excretion.—A negative nitrogen balance develops in the presence of infection (Peters, 1944; Grossman *et al.*, 1945). Nitrogen excretion is very greatly increased in acute infections and to a considerable but less extent in chronic infections (Grossman *et al.*, 1945). The increased nitrogen is excreted in the urine in the form of urea and ammonia. Excretion of creatinine is unchanged. This loss of nitrogen is not definitely related to the febrile reaction (Grossman *et al.*, 1945) in acute infections; it may continue after the patient has become afebrile, and in certain chronic infections it may not continue in spite of continued fever.

Similar changes in blood chemistry are found in experimental animals after the production of a sterile abscess by turpentine injections (Cartwright *et al.*, 1946b). The significance of these metabolic changes in explaining the aetiology of the anaemia is discussed later.

Anaemia of Trauma

During the war observers investigating the blood picture of air-raid and battle casualties were struck by the fall in haemoglobin level that occurred after injury. It was repeatedly discussed, though with the exception of cases of severe burns it received little comment in the literature (Freebody, 1943-4; Vaughan *et al.*, 1946). A similar anaemia may occur after operative intervention which is not preceded by injury (Seaman and Ponder, 1943) and which, as in the cases studied, is not complicated by sepsis or treatment with sulphonamides; the latter often disturbs the picture of trauma. The available data on which to base a description of the anaemia are scanty—in our own series there were only 14 cases, and in none were blood volumes estimated. The picture, however, was similar to that seen in sepsis: a normocytic normochromic anaemia which in some instances became hypochromic and microcytic. This anaemia occurred even with slight trauma—for instance, in a man with a simple fracture of the patella.

During the period of falling haemoglobin the reticulocyte count is not raised, but during the period of regeneration there is a rise, often only within normal limits. In the few observations made on red-cell fragility it was not increased. Increased red-cell fragility has been described in the anaemia following severe burns (Shen and Ham, 1943), but it is possible that this results from actual injury to the red cells at the time of burning (Shen and Ham, 1943; Brown *et al.*, 1944). In such cases typical spherocytosis is found in the stained films.

Bone Marrow.—No quantitative or qualitative studies have been made of the bone marrow in anaemia associated with trauma.

Metabolic Characteristics

With the exception of nitrogen metabolism little is known of the metabolic characteristics of anaemia associated with trauma.

Serum Bilirubin.—In the few patients we studied the plasma bilirubin was normal (Vaughan *et al.*, 1946), though directly after the injury it tended to be higher than it was during the period of a rising haemoglobin.

There is no information about the level of the plasma iron or copper, the erythrocyte content of coproporphyrin, or the excretion of coproporphyrin. Observations on faecal urobilinogen are unconvincing (MacLagan, 1945).

Urinary Urobilinogen.—Though in studying air-raid and other civilian casualties quantitative examinations were not made, we were struck with the frequency with which we found considerable quantities of urobilinogen in the urine.

Nitrogen Excretion.—The negative nitrogen balance found in association with trauma is a striking and constant feature emphasized by many observers (Cuthbertson, 1935-6, 1944; Howard, 1945; Stevenson and Bensley, 1947). It occurs after injury or in post-operative conditions. It cannot be entirely prevented by giving high-protein diets, though it can be decreased in severity (Stevenson and Bensley, 1947). During the first ten days after injury nitrogen corresponding to more than 8% of the total body protein may be excreted (Himsworth, 1946-7). On a good diet with approximately 120 g. of protein and 3,000 total calories the average loss of nitrogen in a series of fracture cases was 225 g., or in terms of total protein 1,400 g. This negative balance lasted for an average of 35 days, reaching its maximum at about the sixth day. The recovery was slow. In a group of operative cases the same occurred, but the average loss was only 45 g. and the duration averaged nine days (Howard, 1945). The great difference from patient to patient is noticeable. The excretion is much less in those ill-nourished.

Blood Urea.—Immediately following injury there is a rise in blood urea, which falls to normal levels within the next few days (Vaughan, 1943; Taylor *et al.*, 1943).

Plasma Protein.—After injury, burns, or operative intervention there is often a fall in total plasma protein, but even in those cases in which the total plasma protein remains normal there is a fall in albumin, compensated by a rise in globulin and a rise in fibrinogen (Chanutin *et al.*, 1938; Taylor *et al.*, 1943; Elman, 1944; Croft and Peters, 1945; Vaughan *et al.*, 1946). This finding occurs after slight injury and is associated with only mild degrees of anaemia.

There are thus many striking points of similarity in the morphological and biochemical characteristics in the anaemia associated with sepsis, with sterile inflammatory abscesses produced experimentally, and with trauma. For instance, the anaemia is usually normochromic and normocytic, though it may become hypochromic and microcytic; there is no significant reticulocytosis; red-cell fragility is normal; and in all points on which evidence is available the striking changes noted in metabolism are similar (see Table).

Haematologic and Metabolic Findings in the Anaemia Associated with Sepsis and Trauma

	Sepsis	Trauma
Type of anaemia	Normochromic and normocytic	Normochromic and normocytic
Reticulocytes	Tend to rise with increasing Hb	Tend to rise with increasing Hb
Red-cell fragility	Normal (except some burns)	Normal (except some burns)
Bone marrow	Active	Unknown
Plasma proteins	Serious data; low; albumin down?	Normal or low; albumin down; globulin up
Plasma bilirubin	Normal	Normal
Serum iron	Low	?
Serum copper	High	?
Erythrocyte coproporphyrin	?	?
Urinary and faecal coproporphyrin	?	?
Faecal urobilinogen	Normal	?
Urinary urobilinogen	May be high	?
Nitrogen excretion	Raised; negative balance	May be high
Blood urea	Not known	Raised; negative balance
Treatment	Transfusion; ? cobalt	Increased
Survival transfused cells	Normal	Transfusion Normal?

Treatment

Iron and liver are in general ineffective in the treatment of either condition. There are certain cases of megalocytic hyperchromic anaemia in infants associated with sepsis

which are reported to respond to treatment with liver extract or folic acid. There are cases of hypochromic anaemia associated with both tuberculosis and "rheumatism" which respond to iron, but such cases are exceptional. Recent experimental results on animals suggest that cobalt is worthy of trial (Wintrobe *et al.*, 1947b). Cobalt has long been recognized as a haemopoietic factor in certain anaemias of sheep (Underwood and Filmer, 1935), and it has proved possible to produce experimental polycythemia in many experimental animals by administration of this metal. Wintrobe and his colleagues (1947b) found that rats which became anaemic after the formation of turpentine abscesses—a condition which appears in its metabolic findings to be comparable to infection—responded well to treatment with cobalt. The anaemia was cured though plasma protein and iron remained low. If cobalt was given simultaneously with the turpentine no anaemia developed. The significance of this finding is discussed later.

There is some evidence that a high-calorie high-protein diet may be of value in treating certain aspects of the disturbed biochemistry of trauma (Taylor *et al.*, 1943; Croft and Peters, 1945; Stevenson and Bensley, 1947). Howard (1945) and Stevenson and Bensley (1947) have shown that a high-protein high-calorie diet exerts some sparing action upon protein breakdown, but however much protein is given a negative balance cannot be prevented.

Transfusion of compatible whole blood is at present the only means of restoring haemoglobin and red-cell levels in both types of anaemia.

Aetiology of the Anaemia

What is the cause of this anaemia which is found clinically in association with either sepsis or trauma and which can be produced experimentally by sepsis, by trauma, and by sterile abscesses? It might be claimed that the anaemia of trauma was due to blood loss at the time of injury, but this alone is not sufficient to account for the fall of haemoglobin, though possibly it may be a contributory factor. For instance, the anaemia occurs after a slight injury such as fracture of the patella when there is no obvious blood loss, and it is progressive. Seaman and Ponder (1943) in a study of anaemia following operative intervention estimated the amount of blood lost by measuring the haemoglobin content of all swabs used and found that the fall in haemoglobin was greater than that accounted for by operative loss.

These three conditions have in common the breakdown of body tissues. It is tempting, therefore, to consider the possibility that the anaemia and accompanying metabolic disturbances are in some way dependent upon this common factor. Tissue breakdown is known to liberate many foreign substances, and one or more of these might exert a disturbing effect upon the erythron, causing aplasia, haemolysis, or dyserythropoiesis. On the other hand, the increased demand for tissue-building materials might result in a conditioned deficiency of haemopoietic factors and of other disturbances in metabolism.

It is justifiable to conclude that the anaemia is not dependent upon aplasia of the marrow, since such aplasia is not found, or upon haemolysis, since except in rare instances no destruction of red cells can be demonstrated. In these exceptional cases (Brown *et al.*, 1944; Mollison, 1947) the patient destroys not only his own red cells but also the transfused red cells from a healthy donor unduly fast. In the majority of cases there is no evidence of increased haemolysis. The serum bilirubin level is normal; there is no increased excretion of faecal urobilinogen

(Vaughan and Saifi, 1939), which is present invariably in haemolytic anaemias; and there is no increased detectable destruction of transfused healthy red cells (Brown *et al.*, 1944; Mollison, 1947). The increased urinary excretion of coproporphyrin III already noted (Vaughan and Saifi, 1939) might on theoretical grounds be derived from red-cell breakdown, since only coproporphyrin III is incorporated in the haemoglobin molecule, coproporphyrin I being probably a side-product in the formation of coproporphyrin III. Coproporphyrin III, however, is believed not to be found under any circumstances as a breakdown product of haemoglobin (Watson and Larson, 1947). In known haemolytic anaemias coproporphyrin I is recorded in excess only in the urine (Watson, 1938). The amounts of coproporphyrin III found are also small and are not sufficient to account for the degree of anaemia. It would therefore appear more likely that a disturbance of synthesis at a later stage accounts for the increased excretion of coproporphyrin III (Dobriner *et al.*, 1937; Rimington, 1938).

Dyserythropoiesis, or faulty red-cell production, may be brought about by a variety of means, the commonest of which is a deficiency of haemopoietic factors. There clearly is no lack of the well-recognized haemopoietic factors, since they are ineffective in treatment. The response to cobalt of experimentally produced anaemia of sepsis in rats, mentioned above, suggests that a deficiency of cobalt may be of aetiological significance; further that there may be a conditioned deficiency of one or more amino-acids. Analysis of the facts concerning the metabolic disturbances present in this type of anaemia, details of which have already been given, points to a disturbance in the synthesis of haemoglobin which may prove to be due to such amino-acid deficiencies.

The stages in the synthesis of haemoglobin can be roughly shown as follows:

1. Precursor pyrrole substance $\begin{matrix} \nearrow \text{Coproporphyrin I} \\ \searrow \text{Coproporphyrin III} \end{matrix}$
2. Coproporphyrin III + iron \longrightarrow haematin.
3. Haematin + globin \longrightarrow haemoglobin.

Traces of both copper and cobalt may play a part in either stage 2 or 3.

In the anaemia under consideration there appears to be no failure in stage 1—the formation of coproporphyrin from a precursor—since there is an excess of coproporphyrin in the red cells (Cartwright *et al.*, 1946a). The evidence suggests rather that there is a failure in stage 2 (the junction of iron and coproporphyrin to form haematin) or in stage 3 (the junction of haematin and globulin).

What is known of stage 2? There is an excess of coproporphyrin III excreted in the urine, which may well be due to failure to complete the formation of haematin. There is a lack of iron in the circulating plasma, as shown by the persistent hypoferracemia which precedes the development of the anaemia (Cartwright *et al.*, 1946a). This hypoferracemia is *not* due to an actual lack of iron. Continuous infusion of iron sufficient to maintain a normal plasma iron is unable to bring about haemoglobin synthesis in the presence of infection (Greenberg *et al.*, 1947a). Wintrobe and his colleagues (1947a) by the use of radioactive iron found that iron administered intravenously to a pig with iron deficiency is readily taken up into the haemoglobin molecule, but in the presence of inflammation the uptake of iron to form haemoglobin is greatly decreased, though it returns rapidly to normal if the inflammatory process is checked. The iron is, however, taken up by the liver and spleen—the normal storage depots—in greatly increased quantities. No significant quantity is found in

the inflamed tissues (Greenberg *et al.*, 1947b). Iron is therefore not the limiting factor in the anaemia, though the diversion of iron from the plasma to the storage depots occurs. Wintrobe (1947b) suggested that this diversion is due to lack of cobalt, which they assume is essential to stage 2, the synthesis of haematin. In some way, therefore, not yet clear, the presence of infection necessitates the presence of abnormal amounts of cobalt for the synthesis of haematin. This is, however, extremely speculative. Cobalt might equally well be required in stage 3 of haemoglobin synthesis—namely, the junction of haematin and globin.

In dealing with the anaemia of trauma the hypothesis was advanced from a consideration of a different series of facts that possibly a failure of protein synthesis, presumably globulin, was responsible for this anaemia so affecting the third stage of haemoglobin synthesis (Vaughan *et al.*, 1946). We were impressed by the association of anaemia with a striking fall of albumin and rise of globulin in the plasma in patients without necessarily altering the total circulating protein. This change in relative protein levels is accompanied by greatly increased nitrogen excretion. How far it is related, if at all, to the remarkable changes in at least one proteolytic system of the blood—namely, that concerned with fibrinolysis—also occurring after injury is not yet clear (Macfarlane and Biggs, 1946; Biggs *et al.*, 1947). We must, however, include the anaemia of trauma and of sepsis among the many symptoms indicative of a wide disturbance of protein metabolism.

The cause of this disturbance is obscure. It may be due to disordered liver function following the action of tissue breakdown products—the presence of urobilinogen in the urine and the change in level of albumin and globulin so characteristic of this type of anaemia being also characteristic of liver disturbance. It may, however, be dependent upon a raiding of the protein stores of the body for some particular amino-acid required to restore injured tissues (Croft and Peters, 1945; Howard, 1945; Himsworth, 1946-7). In other words, after injury or infection the body suffers from a conditioned deficiency of some particular amino-acid. It is known, for instance, that both methionine (Glynn *et al.*, 1945) and lysine (Harris *et al.*, 1943) are essential for haemopoiesis. The effects on both the disturbed nitrogen balance and the anaemia of feeding these amino-acids (Croft and Peters, 1945) are at present conflicting.

Summary

It is suggested that the anaemia of trauma and sepsis is dependent upon a disturbance of haemoglobin synthesis affecting chiefly the globin element. This deficiency of globin is part of a wider disturbance of protein metabolism dependent upon the action of breakdown products liberated from the injured tissues or by the need of injured tissues for special amino-acids. Preliminary experimental observations suggest that possibly cobalt may be concerned at some point in this chain of events, but at present the importance of cobalt should not be exaggerated until its value in human cases has been confirmed.

From a practical point of view, apart from all theories as to the aetiology of the anaemia, it is important to treat patients with both trauma and sepsis on a high-protein diet, relieving the anaemia when severe with replacement therapy. It must be remembered, however, that it is not sufficient to provide a high-protein diet: the patient with sepsis or injury rarely feels hungry, and competent nursing care is essential in order to ensure that the necessary food is taken.

The United Nations International Children's Emergency Fund held 14 meetings at Lake Success from Sept. 29 to Oct. 3, 1947. A survey has shown that at least 60 million children in Europe and the Far East need supplementary feeding and other help urgently. The organization now has sufficient funds to start some relief work, though more are still required. Shipments of dried milk, fats, and canned meats from the U.S.A. and Canada have already reached their European destinations.

THE EFFECT OF FOOD SUPPLEMENTS ON POORLY FED WORKERS IN BRUSSELS IN JANUARY, 1945

BY

P. A. BASTENIE, M.D.

AND

P. E. GREGOIRE, M.D.

(From the R.A.F. Institute of Pathology and Tropical Medicine
and the St. Pierre Hospital, Brussels)

In a previous paper (Bastenie, Macrae, Smart, and Yudkin, 1945) the diet of the families of a group of employees at a works in Brussels was described in detail. In order to determine whether the theoretical deficiencies which were found to exist had caused any marked deterioration the effects of the addition of a known supplement to the diet of these men have been investigated. This paper gives an account of the work.

Methods

Experimental Plan

The men, 18 in number, were divided into Groups A and B, containing 10 and 8 subjects respectively. During a preliminary control period of one week two 24-hour samples of urine were collected four and two days before the beginning of the experiment; throughout this period the men were given practice on the use of a dynamometer, and on the last day each man was weighed, the strength of his grip was measured, and an estimate was made of the degree of irritability of his biceps muscle to mechanical stimulation.

A highly nutritious food supplement (Table I) was given to Group A for ten days—designated the first experimental period. During this time Group B received no supplementary food and acted as a control. Four 24-hour samples of urine were collected from each member of both groups on the first, fourth, seventh, and tenth days, and at the end

of the period the weight, grip strength, and muscle irritability were again determined. At each examination care was taken that the subjects arrived in random order so that the observer did not know to which group they belonged.

For three weeks after the first experimental period none of the men in either group received any supplement. During this time, however, one man in Group B became ill and retired from the experiment, and two new men were allocated to this group. A second experimental period of ten days began at the end of the three-weeks interval. Measurements were made of weight, grip strength, and muscle irritability at the beginning and end of the second experimental period, but no samples of urine were collected. During these ten days the men in Group B received a supplement of food similar to but not identical with that given in the first experimental period (Table II), whereas those in Group A received no supplement and acted as controls. During both periods the supplement was consumed under supervision, and emphatic instructions were given to all the subjects that they must continue to eat the usual amount of food at home. Unfortunately supervision could not be exercised over their intake at home.

Measurement of Weight.—The men were weighed at approximately 10.30 a.m. on each occasion. Trousers, trunks, and stockings were worn, but the rest of the clothes were removed before weighing.

Estimation of Grip Strength.—The strength of the grip of the right hand (all subjects were right-handed) was determined on a grip dynamometer, with the right arm close to but not touching the side of the body, the elbow flexed to a right-angle, and the forearm fully supinated and parallel with the ground. Practice was allowed for several days, and when this appeared to be sufficient the estimations were made. Five readings were taken at intervals of 30 seconds. There was no evidence of tiring.

Estimation of Muscle Irritability.—In order to estimate the irritability of the biceps muscle to mechanical stimulation the elbow was flexed to approximately a right-angle, the forearm supported, and the subject told to relax his arm muscles as fully as possible. The centre of the biceps muscle belly was then gripped transversely and quickly nipped and rolled between the observer's thumb and forefinger, the operation being somewhat painful to the subject.

TABLE I.—Daily Intake of Nutrients by Subjects Receiving Food Supplement During Period 1

	Kilo-calories	Protein	Fat	Carbo-hydrate	Calcium	Iron	Vitamin A	Aneurin	Nicotinic Acid	Ribo-flavin
		(g.)	(g.)	(g.)	(mg.)	(mg.)	(i.u.)	(μg.)	(mg.)	(μg.)

* Calculated from data given in previous publication (Bastenie *et al.*, 1945).

In all subjects a raised ridge appeared in the region stimulated (see illustration). The time during which this ridge persisted was taken as an index of the irritability of the muscle. Five estimations, all on the right biceps muscle, were made on each occasion.

Photograph showing response of biceps muscle to mechanical stimulation.

Urinary Analysis.—The total volume of each of the 24-hour samples of urine was measured, and after acidification with 4 ml. of 2N. H₂SO₄ per 100 ml., was kept for analysis. The total nitrogen was estimated by the Kjeldahl method.

Food Supplements.—All subjects normally had a small midday meal at the works. During the periods of supplementation the experimental groups received highly nutritious dehydrated foods at midday in addition to their normal factory meal. The food supplements consisted almost entirely of milk, cheese, butter, and eggs; in the second experimental period beef was added. The nutritive value of the supplements given during the two periods is shown in Tables I and II, respectively. The dehydrated food, apart from the beef, was specially prepared by the Low Temperature Research Station, Cambridge. After dehydration the food was moulded into blocks each weighing about 50 g. and suitable for one helping (see de Rousset-Hall and Ingram, 1945). The advantages of this arrangement are many: there is no need to weigh the food before each meal, since it is only necessary to count a suitable number of blocks for reconstitution; there is an assured uniformity in the food given on different days, since the whole of the amount required for the experiment can be prepared in advance; the keeping qualities are excellent; the low weight and small bulk facilitate transport; and the uniformity of the experimental diet enables a great saving to be made in the analysis of foodstuffs.

Results

The average values of weight, grip, and muscle irritability of subjects are shown with the appropriate standard errors in Table III. It will be seen that, whereas there were no significant changes during the experimental periods in the control group, the group which received a supplement in

both experimental periods did change, there being an increase in weight and grip and a decrease in the length of time for which local contraction of the biceps muscle persisted after mechanical stimulation.

The results obtained from these measurements may be expressed in a different way. Seventeen of the subjects were on different occasions in both the experimental and the control group. The different changes in these individuals when they acted in each capacity may therefore be com-

TABLE IV.—Average Difference in Change in Weight, Grip, and Muscle Irritability of 17 Subjects When Acting as Control and When Receiving Supplementary Food

Significance of differences of changes in Groups A and B: $P = 0.053$

been excluded from Group A and one from Group B in calculating these averages, since the 24-hour specimens of urine presented by them were obviously false. Both the experimental and the control group showed a significant increase in urinary nitrogen excretion during the experimental period; although the increase was somewhat greater in the experimental group than in the control group, this might possibly have been due to chance.

Discussion

The workers under investigation obtained from their ordinary diet about 12 g. of nitrogen a day (Bastenie *et al.*, 1945). They excreted 9 g. in the urine, and, assuming the faecal excretion to be about 1.5 daily and that the same amount was lost in sweat (Cuthbertson, McCutcheon, and Munro, 1937), it would seem that they were in nitrogen equilibrium.

* One subject is not included in these figures, as he became ill during the second experimental period. Two new subjects are included in Group B for the same period.

While the men were acting as experimental subjects both the protein and the calorie intakes were increased to a theoretical level of about 130-145 g. of protein and 3,700 calories daily. It was of course impossible to guarantee that they ate as much at home as they did when not receiving the supplement, although they were asked to do so: the above values are maxima, and it is probable that the actual total intakes were somewhat lower.

Under the dietary conditions resulting from the consumption of the highly nutritious food supplement the daily urinary output of nitrogen rose from an average of 8.5 g. to 10.9 g., an increase of only 2.4 g.; the control Group B showed an increase from 9.5 g. to 10.8 g. In Group A, allowing for sweat and faecal loss, there must have been a total daily elimination of nitrogen per man of about 14 g. Since, provided the experimental subjects continued to eat the same foods at home when they were receiving the supplement, they had a daily nitrogen intake of about 21 g. per man, they must have retained about 7 g. of nitrogen per man daily. According to Rubner (1898), 1 g. of retained nitrogen gives 33 g. of tissue, mostly muscle. Thus in ten days the experimental subjects (Group A) should have gained 2.3 kg. In fact, they gained on the average 1.3 kg. This difference between the theoretical gain in weight and that which was actually found was not likely to be due to a loss in body fluids, since the 24-hour urinary volumes of subjects in Group A were never significantly different from those of the control subjects or from the volumes obtained during the preliminary period. It is improbable that either the experimental error or inaccuracies in Rubner's factor could account for all the discrepancy, and it seems most likely that the men did not in fact continue to eat the same amount as usual in their homes while receiving the experimental supplement. If we assume that Rubner's factor is reasonably accurate, they should have been receiving 100 g. of protein per man daily; in other words they must have consumed about 60% of the protein in their normal daily ration at home while receiving the food supplement. Cuthbertson *et al.* (1937) and Cuthbertson and Munro (1937) showed that subjects who were adequately fed retained over a period of eight days about 40% of the nitrogen of a milk or similarly constituted food supplement to their normal diet. In the present experiment the food supplement had a calorie-protein ratio similar to that of the supplement fed by Cuthbertson *et al.* The subjects in Group A excreted on the average an extra 2.4 g. of nitrogen per man daily while receiving the supplement and those in Group B (control) 1.3 g. during the same period. Thus it can be considered that the extra food received by Group A resulted in an increase in the daily urinary nitrogen excretion of about 1 g. per man, which on the basis of Cuthbertson's findings would have resulted from an extra intake of about 1.7 g. of nitrogen or about 10 g. of protein. They were, however, supposed to be receiving an extra 56 g. of protein per man daily, and, calculated theoretically on their gain in weight, using Rubner's factor, they received at least 25 g. extra per man daily. The nitrogen retention from the food supplement was thus more than twice as great as that found by Cuthbertson *et al.* (1937) and Cuthbertson and Munro (1937) for normally fed individuals. On these grounds it seems reasonable to conclude that the experimental subjects were in equilibrium on a plane of nitrogen metabolism lower than that encountered in subjects who are considered to be well fed.

There was a gain in grip strength and a decrease in muscle irritability to mechanical stimuli during the experimental period, and it is of interest to consider whether these factors can be related to the gain in weight or to the nitrogen retention. Consideration of the variations in weight, grip,

and muscular irritability of each of the subjects in the present investigation revealed no significant correlation between change in weight and change in muscle irritability or change in grip strength, between nitrogen retention and change in muscle irritability or change in grip strength, or between change in muscle irritability and change in grip strength.

The abnormal irritability of muscles to mechanical stimuli was first described by Schiff (1858-9) and later investigated in greater detail by Cursehmann (1905), Langley and Hashimoto (1918-19), and Denny-Brown and Pennybacker (1938). There is no very definite evidence that would indicate which biochemical lesion produces the hyperirritability; the most that can be said is that the phenomenon is increased by the conditions which interfere with normal muscle metabolism. There seems to be little doubt that the duration of the ridge in the Belgian workers (about 4.5 seconds) was abnormally long before they received the supplement (the mean duration in healthy R.A.F. subjects has been found to be 2.1 seconds), and that the supplementation did result in a decrease in the duration of the phenomenon. Initially also there was a strikingly significant inverse correlation between the strength of grip and the duration of the ridge of localized contraction following mechanical stimulation ($r = -0.77 \pm 0.092$).

The gain in grip strength which occurred during supplementation is also statistically significant, but unfortunately it is impossible to eliminate the psychological factor. There is likely to be a greater urge to try hard in a subject who is receiving extra food than in one who is living on short rations, and it is impossible to provide a "dummy" substitute for food in control subjects.

In conclusion it has been shown that the addition of supplementary foodstuffs to the defective diet of Belgian workers produced a considerable retention of nitrogen, a gain in weight, an increase in muscle strength, and a decrease in the irritability of muscle to mechanical stimuli. None of these changes, however, could be correlated when consideration was given to the changes occurring in each individual, nor was it possible to correlate any of the changes with the intake of any particular nutrient.

Summary

A group of workers in Brussels in 1945 who were receiving inadequate food were given a supplement to correct the deficiency, and the effects of this supplement on the weight, the grip, the urinary nitrogen excretion, and the irritability of muscle to nipping were measured; their values were compared with those given by a control group receiving no supplement.

The average weight increased significantly in the experimental groups during the ten days of supplementation, as did the strength of the grip; the duration of the local contraction of the biceps muscle which followed mechanical stimulation decreased significantly.

There was a marked retention of nitrogen during the period of supplementation; the large increase in protein nitrogen intake resulting from consumption of the supplement caused no pronounced increase in urinary nitrogen output.

The significance of myotatic irritability has been discussed and an inverse correlation was shown to exist between it and strength of grip.

No relationship could be demonstrated between individual changes in weight, nitrogen retention, grip, or muscle irritability.

We wish to thank Air Marshal Sir H. E. Whittingham, the Director-General of Medical Services, Royal Air Force, and Air Commodore T. McClurkin, Director of Hygiene, for their encouragement in this work; also the Director of the Electro-Gaz Works, Brussels, for permission to carry out the experiments, the social workers there for their invaluable help, and the subjects for

willingly submitting to the experimental procedures. The determinations of urinary nitrogen were carried out by Flight-Sergeant G. A. Childs under very great difficulties, and we accord him our thanks and appreciation.

An essential for the carrying out of this experiment was the provision of food blocks, and we thank Dr. F. Kidd, the then Director of the Low Temperature Research Station, Cambridge, and Dr. M. Ingram and Mr. O. de Roussel-Hall of his staff, who supervised the manufacture of the blocks.

VIABILITY OF STRANGULATED BOWEL

INTERIM REPORT OF SURGICAL SUBCOMMITTEE OF THE CLINICAL RESEARCH COMMITTEE OF THE PUBLIC HEALTH DEPARTMENT OF THE LONDON COUNTY COUNCIL*

This committee is at present organizing a study of the condition and fate of strangulated bowel, with the object of determining the correct operative procedure to be undertaken when confronted with recently strangulated bowel of doubtful viability, and the following preliminary conclusions have been drawn from an initial series of 336 operations.

The main statistical tables form appendices to this report. Where statements in the report require more detailed statistical illustrations reference is given (by a letter in parentheses) to the appropriate paragraph of the notes which follow the main tables.

Causes of Strangulation

In the whole series of cases—68 (20.2%) of which were fatal—the percentage distribution of causes of strangulation, which excluded intussusception, was as follows:

Hernia	Inguinal ..	31.8	91.9
	Femoral ..	46.9	
	Umbilical ..	4.5	
	Incisional ..	4.8	
	Obturator ..	1.2	
	Internal ..	2.7	
By band or adhesions		6.0	2.1
By volvulus ..		2.1	

Ultimate Condition of Strangulated Bowel

The main object of the research—namely, the discovery of the features which give a clue to the ultimate fate of the strangulated bowel—may be approached in several ways. These may be briefly enumerated and commented on as follows:

1. If a patient dies of bowel gangrene after the strangulated bowel has merely been replaced in the abdomen when dealing

*The members of the surgical subcommittee are: Mr. J. E. Piercy, New End Hospital; the late Mr. G. F. Stebbing, Lambeth Hospital; Mr. N. C. Tanner, St. James Hospital; Mr. J. R. M. Whigham, St. Andrew's Hospital; Mr. C. R. Boland, Mile End Hospital; Mr. F. D. Murphy, Futham Hospital. The convener of the subcommittee was Mr. Tanner, who with Mr. Stebbing was mainly responsible for the report. The statistical analysis was made by the staff of the statistical section of the Public Health Department under the direction of Mr. B. Benjamin.

† Left the Council's service before the completion of the report.

with the strangulating agent, and this has been confirmed at necropsy, then the state of the bowel as noted at operation will give valuable information. The following three cases were reported in which this had occurred.

(i) Case A. B., aged 53. Necrotic purulent ulceration of the mucosa was noted at necropsy. Death occurred eight days after operative relief of strangulation. At the operation it was recorded that 400 cm. of the whole circumference of small bowel was involved, partly by strangulation, partly by secondary mesenteric thrombosis, and that it was plum-coloured with white constriction rings. After release of the strangulation it remained plum-coloured. The bowel was flabby but the surface was shiny, and muscular contractions of the wall were seen. Oxygenation of the patient caused no change in the colour of the bowel. Pulsation was present in the mesenteric vessels.

(ii) Case C. D., aged 34. Gangrene of bowel was discovered at necropsy. Death occurred seven days after operative release of the strangulation. At the operation 50 cm. of the whole circumference of small bowel was found to be plum-coloured but shiny, with normal tonus in the wall. Muscular contractions were seen. Pulsation was present in the mesenteric vessels.

(iii) Case E. F., aged 83. Gangrene of bowel was discovered at necropsy. Death occurred 13 days after operative release of the strangulation. At the operation 60 cm. of the whole circumference of small bowel was found to be plum-coloured but shiny, with oedema of the wall. Muscular contractions were seen. Pulsation was present in the mesenteric vessels.

In each of these cases 50 cm. or more of bowel was involved, but the state of the bowel as noted at operation was no worse than that in many cases which recovered. It seems a reasonable conclusion that risk of subsequent gangrene is greater where a long length of bowel is strangulated than where a short length is involved [Appendix II. (a)].

2. If a patient has a secondary operation for gangrene or damage of bowel after having had a simple "replacement," "untwist volvulus," or "divide constricting band," then the state of the bowel as noted at the original operation would give important data. No case was reported in which total gangrene of a segment of bowel occurred after replacing it in the peritoneal cavity, but in two cases stenosis of the bowel, with peritoneal adhesions, supervened, suggesting that some degree of mucosal and perhaps peritoneal damage had occurred and that the replaced bowel was on the borderline of viability:

(i) Case G. H., aged 51. Had replacement of bowel 30 hours after the onset of hernial strangulation. State at original operation: 12.5 cm. of small intestine was strangulated, black in colour, with grey constriction rings, improving in colour after release of strangulation. Surface of bowel was shiny, and wall flabby; muscular contractions in bowel wall were absent, and pulsation in mesenteric vessels was present. Thirty-six days later a second operation was necessary and 20 cm. of ileum was resected for adhesion and stenosis.

(ii) Case J. K., aged 44. Had replacement of 7 cm. of small intestine 9½ hours after onset of strangulation. At the operation the bowel was plum-coloured and oedematous, with a shiny surface which became mottled after release of strangulation. There were muscular contractions in the bowel wall and pulsation in the mesenteric vessels. Gripping abdominal pains followed after discharge from hospital, and 28 days after the first operation a second operation was necessary and the previously strangulated bowel was seen to be stenosed, with peritoneal adhesions.

3. An examination was made for cases where bowel, coloured before or after release of strangulation black, grey, green, or yellow, was replaced. There were 20 patients with bowel of one of these colours, of whom 14 survived, giving a mortality of 30%. Among 216 "replacement" cases in which the bowel colour was normal the mortality was only 9.7% ($\chi^2 = 7.42$; $P = 0.006$).

4. Twenty-one cases were recorded in which muscular contractions in the bowel wall were absent and the bowel was replaced. Fifteen of these survived, giving a mortality of 28.6%, as compared with a mortality of only 8.6% in 197 "replacement" cases with contractions present ($\chi^2=7.95$; $P=0.005$).

5. If pulsation in mesenteric vessels is absent in the strangulated segment of bowel in "replacement" cases the outcome is important. There were two such cases with pulsation absent and neither survived. In 214 "replacement" cases with pulsation present the mortality was 10.7%. The probability of such a difference in mortality occurring by chance is 0.013.

Other Findings

Other items of interest have emerged which are not directly connected with the main research.

Records of the duration of strangulation at time of operation show that inguinal herniae tend to come to operation earlier than femoral herniae (b). While there is no significant difference in average age (c), the more obvious nature of the lesion, the more insistent pain in the sac (d), and the earlier onset of vomiting (e) in inguinal cases make this not unexpected. This shorter duration of strangulation probably accounts for the lower mortality in strangulated inguinal herniae. Taking all strangulations together it is found that the case mortality increases with the duration of strangulation, though a larger series of cases will be required before one can expect to find any

significant difference between case mortality at 0-6 and 6-12 hours (f).

An analysis of the state of the bowel wall for all cases showed that 20.6% were normal, 52.8% were oedematous, 15.3% were flabby, 16.0% were clearly gangrenous, and 5.8% were perforated. The greater percentage of gangrenous and perforated bowel in the femoral herniae is associated with the increased delay before operation and probably also with the increased frequency of Richter herniae in femoral hernia (g):

Whole circumference involved	Inguinal Hernia	Femoral Hernia
Part of circumference involved	89.9%	77.2%
	10.1%	22.8%

Operative Procedure

The figures were investigated to see whether they would provide the surgeon with practical guidance to the best type of anastomosis to perform after resection. Of the cases having a resection, 20 were resections and lateral anastomosis, and 9 died—a mortality of 45%; 32 were resections and end-to-end anastomosis, and 18 died—a mortality of 56.3%.

The figures do not show any statistical difference between lateral anastomosis and end-to-end anastomosis ($\chi^2=0.62$, $P=0.43$), and we must await larger numbers before reliable conclusions can be drawn.

The subcommittee wishes to express its thanks to Sir Allen Daley, County Medical Officer of Health, for the encouragement of this research and to all those who have co-operated.

APPENDIX II

Statistical Notes

(a) Length of Bowel Strangulated (Replacement, etc.,* Cases Only)

Length of Bowel Strangulated	Cases†	Deaths	Mortality (%)
1-3 cm. ..	20	2	10.0
3-5 " ..	34	4	11.8
5-7 " ..	47	7	14.9
7-10 " ..	26	—	—
10-15 " ..	35	2	5.7
15-25 " ..	34	5	14.7
25-35 " ..	14	1	7.1
35-50 " ..	6	2	33.3
50-100 " ..	6	3	50.0
Over 100 cm. ..	1	1	100.0
Total ..	223	27	12.1

* Includes replacement, untwist volvulus, divide band, etc.
† In which length of bowel strangulated was stated.

None of the above differences in mortality is statistically significant individually. On grouping, however, the following comparison can be made :

Length of Bowel Strangulated	Cases	Deaths	Mortality (%)
Under 15 cm. ..	162	15	9.3
Over 15 " ..	61	12	19.7

This difference is statistically significant ($\chi^2 = 4.50$; $P = 0.034$).

(b) Duration of Strangulation

Duration (Hours)	Type of Hernia			
	Inguinal		Femoral	
	No.	%	No.	%
0-6 ..	20	19.4	15	10.3
6-12 ..	27	26.2	28	19.2
12-24 ..	14	13.6	24	16.6
24-48 ..	25	24.3	28	19.3
Over 48 ..	17	16.5	51	35.2
Total ..	103	100.0	146	100.0

Of strangulated inguinal herniae 59.2% came to operation within 24 hours, as compared with 46.1% of strangulated

femoral herniae. This difference is statistically significant ($\chi^2 = 4.30$; $P = 0.038$).

(c) Age of Patient

Type of Hernia	Mean Age	Standard Error
Inguinal ..	63.8 years	1.3
Femoral ..	63.2 "	1.0

The difference is clearly not statistically significant.

(d) Pain in Sac

Type of Hernia	Cases with Pain Recorded	Cases with Duration of Pain less than 48 Hours at Time of Operation	
		No.	%
Inguinal ..	71	57	80.3
Femoral ..	100	68	68.0

This difference is hardly statistically significant ($\chi^2 = 3.19$; $P = 0.074$) but does suggest that the duration of pain is strongly correlated with the duration of strangulation, and this is consistent with the hypothesis that the more insistent pain in inguinal cases is a factor in bringing them to operation earlier than the femoral cases.

(e) Duration of Vomiting

Much the same argument applies to the experience of onset of vomiting. The coefficient of correlation between duration of strangulation and duration of vomiting is +0.95 for both inguinal and femoral herniae. Alternatively we may approach the problem in this way: if vomiting occurs earlier after strangulation in inguinal herniae then we should expect to find fewer long-duration strangulations associated with short-duration vomiting. This is true, as the following figures show.

Type of Hernia	Cases*	Cases with Strangulation longer than 24 Hours but Duration of Vomiting less than 24 Hours	
		No.	%
Inguinal ..	73	6	8.2
Femoral ..	117	14	12.0

* In which both durations were recorded.

This difference is not by itself statistically significant ($\chi^2 = 0.67$; $P = 0.41$), but in view of the alternative evidence of correlation might be accepted.

(f) Case Mortality and Duration of Strangulation

It will be clear from Section B of Table I that there is a progressive rise in mortality as the duration of strangulation increases. The slight reduction after 24 hours (from 16.7 to 15.2) is probably only a sampling irregularity and is not statistically significant.

With regard to Table III, owing to the reduction in the number of cases involved in the classifications of this table the differences in mortality reach statistical significance only when a broad comparison is made between strangulation of less than 48 hours and strangulation of longer duration than 48 hours—viz. :

Duration of Strangulation (Hours)	Operative Procedure								
	Replacement, etc.*			Oversew†			Resection‡		
	Cases§	Dths.	Mort. %	Cases§	Dths.	Mort. %	Cases§	Dths.	Mort. %
Under 48 ..	176	15	8.5	16	2	12.5	23	8	34.8
Over 48 ..	45	11	24.4	15	6	40.0	29	19	65.5

* Includes replacement, untwist volvulus, divide band, etc.
† Includes oversew doubtful area and oversew constriction ring.
‡ Includes resection with lateral anastomosis, end-to-end anastomosis, etc.
§ In which duration of strangulation was stated.

The increase in mortality with longer duration of strangulation is significant for both replacements ($\chi^2 = 8.76$; $P = 0.003$) and for resections ($\chi^2 = 4.85$; $P = 0.028$). The difference in mortality for the small number of oversew cases is not by itself statistically significant, the exact probability being 0.09.

(g) Gangrene and Perforation in Femoral Herniae

Type of Hernia	Cases*	Gangrenous and/or Perforated Bowel Wall	
		No.	%
Inguinal	106	13	12.2
Femoral	150	24	16.0

*In which the state of the bowel wall was recorded.

This difference is not quite large enough to be statistically significant ($\chi^2=0.70$; $P=0.40$).

The higher incidence of Richter herniae in femoral hernia recorded in the text of the report (22.8% against 10.1% in inguinal hernia, a difference of 12.7 ± 4.6) is statistically significant.

EOSINOPENIA CAUSED BY ADRENALINE INFUSION AND BY INSULIN HYPOGLYCAEMIA

BY

Z. Z. GODLOWSKI, M.D.

Lecturer in Physiopathology and Clinical Medicine at the Polish Medical School, Polish Medical Centre, Edinburgh.

Insulin hypoglycaemia was found to have a beneficial effect in the treatment of all except one of a series of cases of allergic bronchial asthma (Godlowski, 1946). The cases which responded were characterized by a fall in the eosinophil count of the blood, whereas no such fall was observed in the remaining cases with early recurrence of symptoms. The return of the blood eosinophils to normal in these responding cases took place in an oscillating fashion. Such an oscillatory return of the blood eosinophils has also been observed by Spangler (1925) during non-specific desensitization of bronchial asthma cases.

The blood eosinophils in the present allergic cases were observed to vary considerably in the same subject during the 24 hours in which hypoglycaemia was induced, and regularly to such an extent as to exclude any error in calculation. The significance of this phenomenon is made clear by two sets of observations. First, Bertelli *et al.* (1910) produced a considerable eosinopenia in dogs by hypodermic or intravenous injections of adrenaline. Secondly, Cannon *et al.* (1924) experimentally, and Heilbrun and Libert (1939) clinically, found that insulin hypoglycaemia is characterized by a liberation of adrenaline in an amount sufficient to meet the emergency of the rapidly falling blood sugar. These observations suggest that the eosinopenia occurring during insulin hypoglycaemia is due to an outpouring of adrenaline. Such a theory was accordingly put to the test by studying 11 allergic and eosinophilic subjects (9 bronchial asthma, 1 urticaria, and 1 dermatitis) along the following lines.

Method

The preliminary examinations of the allergic cases consisted in x-ray examination of the chest and sinuses, exploration of the upper part of the respiratory tract, urine analysis, investigation of the sputum for eosinophilia and of stools for parasitic infestation and eosinophils, a test meal, the B.S.R., and white cell and differential counts.

The non-fasting blood eosinophils were estimated before starting the adrenaline infusion. The infusion consisted in the intravenous administration of 8 to 10 ml. of 0.1% adrenaline solution (i.e., 8 to 10 mg. of adrenaline) dissolved in 200 to 300 ml. of normal saline at the rate of 6 to 12 drops a minute over a period of 8 to 12 hours. Severe palpitation, headache, or other toxic symptoms of hyper-

adrenalinaemia were relieved by slowing or stopping the drip for a short time and then gradually increasing up to the limit of tolerance. The blood pressure rose in the first hour and then fell slowly almost to its initial level during the second hour of the drip. A few minutes after the drip started a feeling of relief resulted in severe cases. The eosinophils were estimated half-hourly during the first three hours (by the method used during insulin hypoglycaemia), then hourly until the patient fell asleep; the eosinophil count during the next two hours was taken twice by squeezing the already pricked finger without waking him.

Two or three days later the insulin test was made (after 12 hours' fast) by injecting 100 units of soluble insulin subcutaneously, and the same examinations were carried out as during the adrenaline infusion. The patients were not kept in a state of hypoglycaemia longer than three hours, and hypoglycaemia was stopped by oral or intravenous introduction of glucose (Godlowski, 1946). Counting of the eosinophils and other white cells was done according to the method described by Randolph (1944) or by estimating the differential count of a blood film stained by the May-Grünwald-Giemsa technique.

The first six cases of bronchial asthma and one case of allergic dermatitis were subjected to sternal puncture before and during the eighth hour of adrenaline drip and insulin hypoglycaemia, and the bone marrow obtained thereby was examined for eosinophils in the same way as the peripheral blood.

Results and Discussion

All the cases examined during adrenaline infusion (curve 1) showed a marked eosinopenia amounting in most instances to a complete disappearance of eosinophils from

the blood. Such a disappearance took place within half an hour in two cases, whereas the remainder required a period of several hours to reach the zero level or near it. The lowest level was in the more prolonged cases reached during the fourth hour of adrenaline infusion and oscillated around this for the next six hours. Thereafter the curve of mean values, although the adrenaline infusion was

discontinued, remained at the same level, and in the first hour of sleep climbed steeply, but not to its initial level. The pre-experimental value was attained next morning—that is, 24 hours after the start of adrenaline infusion.

Insulin hypoglycaemia (curve 2) was also accompanied by a disappearance of eosinophils from the peripheral blood. This diminution of cells, however, differed from the

eosinopenia of the adrenaline drip in that it began a little later, took place more slowly and steadily, and did not last so long. The curve of mean values then slowly climbed and became very steep in the first two hours of sleep before reaching its initial level next morning.

The quantitative and qualitative similarity of eosinopenia in adrenaline infusion and in insulin hypoglycaemia suggests a common cause for both, particularly in view of the proved fact of adrenaline production in insulin hypoglycaemia both in laboratory (Cannon *et al.*, 1924) and in clinical experiments (Heilbrun and Libert, 1939).

The sternal bone-marrow eosinophilia in seven cases at the time of lowest peripheral eosinophilia remained at its initial level during both adrenaline infusion and insulin hypoglycaemia. The conclusions from this are (a) that adrenaline in both cases did not exercise its depressive action on bone-marrow eosinophilia, and (b) that bone-marrow cannot be the site where eosinophils accumulate during adrenaline infusion and insulin hypoglycaemia.

The question of eosinopenia during adrenaline infusion and insulin hypoglycaemia necessitates a consideration of the following problems: (1) the mode of adrenaline action in the eosinopenia due to exogenous and endogenous hyperadrenalinaemia; (2) the site of eosinophilic retention during that time; and (3) the relation between artificial eosinopenia and sleep.

(1) Adrenaline injected intravenously performs its action almost immediately by stimulating the sympathetic nervous system; but this action is very quickly exhausted, since adrenaline itself is rapidly metabolized by the tissues. The effect of sympathetic stimulation, however, might persist for a prolonged period, as, for example, neutrocytosis (Naegeli, 1931). One of these prolonged sympathetic effects might be eosinopenia, whereas eosinophilia belongs to the so-called vagal symptoms (Eppinger and Hess, 1909a, 1909b). The mechanism of this action of adrenaline cannot itself be explained on the ground of the results of the present observations.

(2) The values obtained for bone-marrow eosinophilia definitely exclude the retention there of both young and mature eosinophils. Bertelli *et al.* (1910) showed that eosinophilia due to intravenous or subcutaneous injection of 5 mg. of adrenaline into a dog produced in three and a half hours a fall in eosinophils from 6.9% with a total white blood count of 12,050 to 3.5% with a total of 20,050, the other white cells being more or less in the same proportion as before injection. A histological search for local eosinophilia after death showed that the liver was the only organ with an abnormally high value for eosinophils. Those authors therefore believe that liver tissue absorbs the surplus adrenaline, and by destroying it rapidly liberates itself from its eosinopenic action, while the eosinopenic influence is still evident in the other organs.

(3) Sleep is accompanied by symptoms of vagal preponderance, and the eosinopenia resulting from transitory artificial sympathetic overactivity accordingly loses its causative stimulus. The return to initial "vagal blood," however, needs a longer vagal action of sleep than two hours.

Continuation of endogenous hyperadrenalinaemia produced by repeated insulin hypoglycaemia might in a certain number of allergic cases result in a more permanent depression of the high eosinophilic count, and this in turn could be regarded as an indication of a return towards the normal. Clinical improvement of bronchial asthma and other allergic conditions (Godlowski, 1946) following the application of insulin hypoglycaemia and accompanied by diminishing eosinophilic count might be due to the increased production of endogenous adrenaline. The eosinopenia occurring during preliminary insulin test, on the other hand, may be regarded as a proof of an ability of the organism to respond by transitory adrenalinaemia. This might be taken as suggesting that the organism is likely to respond to such a treatment.

Summary

A study is made of 11 allergic and eosinophilic subjects to test the suggestion that the eosinopenia occurring during insulin hypoglycaemia is due to the outpouring of adrenaline.

It was found that peripheral blood eosinophilia decreases markedly and to the same extent during prolonged intravenous adrenaline infusion as during insulin hypoglycaemia.

Sternal Bone-marrow Eosinophilia in Adrenaline Infusion and Insulin Hypoglycaemia

No.	Before Treatment				During 8th Hour of Adrenaline Infusion				During 8th Hour of Insulin Hypoglycaemia			
	Young Forms %	Mature Forms %	Total %	Periph. Eo-philia %	Young Forms %	Mature Forms %	Total %	Periph. Eo-philia %	Young Forms %	Mature Forms %	Total %	Periph. Eo-philia %

	Average:			11.8			11.0	3.3			11.2	7.3

* A case of allergic dermatitis not included in cases described in text.

The quantitative and qualitative similarity of this phenomenon in both conditions suggests a common cause for the eosinopenia.

Adrenaline does not affect the eosinophilic content of bone marrow, and the latter accordingly is not the site of eosinophilic retention.

Eosinopenia due to sufficiently high insulin dosage indicates an ability of the organism to meet the emergency of hypoglycaemia by secreting adrenaline, and this, if repeated several times, might explain the improvement reported as being effected in allergic conditions through treatment with insulin hypoglycaemia.

THE CONVULSIVE PROPERTIES OF THIOPENTONE

BY

R. L. WYNNE, M.B., M.R.C.S., D.A.
 Anaesthetist, Birkenhead General Hospital

The case of frank convulsions under thiopentone anaesthesia recorded by Bodman and Farr (1947) is of interest inasmuch as such phenomena in slighter form must have been widely observed but hitherto seem to have excited little or no remark in the literature other than an occasional reference to "tremors."

Thiopentone is a drug not distantly related to others—e.g., 1-3-dimethylbutylethyl barbituric acid, and 2-1-methylcrotyl-2-methylallyl-, 1-methylbutyl-2-methylallyl-, and crotyl-*n*-butyl thiobarbituric acids—which have been

described by Swanson and Fry (cited by Adams, 1944) as convulsants having no sedative properties.

The "tremors," or minor convulsive manifestations, of thiopentone occur shortly after consciousness is lost, and consist of: (1) Pronatory spasm of the arm, either spontaneous or readily elicited by pricking, or even simply by withdrawal of the syringe needle. (2) This in some cases progresses to strong clonic contractions of the pectoral and neighbouring muscles, a sign which might perhaps be descriptively named the "shudder reflex." (3) Other muscles, especially those of the glottis and diaphragm, may be involved. The phenomena are in all cases most strongly grouped round the musculature associated with respiration, normal or forced. (4) In some cases the spasm is of tonic rather than clonic nature. These are harder to recognize, since the predominant sign is a cessation of respiration, which more often occurs as indicating a relaxation of the musculature consequent on a momentary overdose. The spastic type of respiratory arrest may, however, be differen-

tiated by its occurrence after a relatively small dose and almost invariably in the muscular type of patient, by observation of the rigidly held chest, and by the fact that it often disappears on rapidly administering a further small dose of the drug (though it is not recommended that this last feature be adopted as a routine test).

The following case is cited in illustration.

Case Report

A healthy gunner aged 33 was presented for anaesthesia following a fracture of both bones of the left leg, the date being Oct. 11. After "omnopon"—scopolamine he was given 1 g. of thiopentone intravenously, combined with gas-oxygen, for skeletal traction by a pin through the os calcis, and plaster. No untoward symptoms were noted. On Oct. 29 he was anaesthetized for replastering, again receiving omnopon-scopolamine and 1 g. of thiopentone. This time no inhalation was given, and a further injection of 0.5 g. of thiopentone was found necessary; otherwise there were no unusual features.

On Nov. 2 further manipulation was required and he was once more anaesthetized, on this occasion for some reason without any premedication. He was given 1.5 g. of thiopentone, and definite convulsive phenomena at once developed. Pronatory movements were followed by the "shudder reflex" described above, and this by convulsive inspiratory movements of the respiratory musculature. Respiration became shallow and rapid, the movements being about 60 a minute, and thus frequent enough to ensure adequate oxygenation. During the next five minutes the signs died away, and the patient thereafter progressed without further unusual signs.

On Nov. 5 another anaesthetic was required, and this time being forewarned, he was given omnopon-scopolamine, and 0.5 g. of thiopentone was injected to see what the response would be. As soon as he became unconscious the same strong convulsive movements were once more observed, and no time was lost in administering gas-oxygen with ether. The administration was rendered difficult by laryngeal spasm, and not until a tracheal tube was passed was the anaesthesia free from difficulty. The patient thereafter progressed normally, and was not seen again.

Comment

This case illustrates other features associated with the properties of thiopentone: (1) The untoward signs were not at first elicited, but developed and got worse after several administrations of the drug during a comparatively short period, presumably indicating a progressive intolerance which might possibly be seen in other cases were their apparent tolerance subjected to the same test. (2) Though premedication was not, in itself sufficient to prevent the signs, its absence on one occasion was associated with their appearance in fully developed form. (3) The condition was readily controlled by combination with other anaesthetic agents. (4) The condition each time occurred so early that it must be regarded as produced by the direct effect of the drug on the nervous system, and not by ketosis, carbon dioxide excess, or any of the other metabolic factors which have in the past been suspected as causative in other forms of convulsions.

My records contain several cases in which so similar a procession of events occurred that it seems needless to recount them in detail. Army experience taught me to regard the occurrence of any degree of spastic pronation during administration as a warning that the subject was unsuitable for uncombined thiopentone anaesthesia, and to add gas-oxygen inhalation in 25% mixture at the earliest opportunity. I always found that two to five minutes of this would ablate all convulsive phenomena and produce an even anaesthesia which could be managed by ordinary methods. Laryngeal spasm and the "total" respiratory spasm described above can usually be ablated by a further dose of thiopentone, but the "shudder reflex" is never thus amenable without the addition of other agents.

Cystoscopy or the passage of bougies under uncombined thiopentone anaesthesia has in my experience often produced difficulties resolved by the addition of gas-oxygen, and the inference seems to be that the sphincters may also be involved in a spastic process during such anaesthesia, which in these cases is also best combined with inhalation agents.

It is curious that these by no means rare signs should occur with a drug often used to combat convulsions; and in this connexion the hypothesis of Williams and Sweet (1944) seems to be pertinent. In considering anaesthetic convulsions in general, they adduce the probability of a constitutional factor, and suggest that in every case a convulsion is "primarily due to an inborn but latent epileptic liability . . . factors which arise during anaesthesia being merely precipitants of the convulsions." Encephalograms of patients known to have had convulsions during anaesthesia show irregularities supporting this hypothesis. Given the existence of such a type of patient, it should not be too much to suppose that the sudden addition of any potent drug to the blood stream might well act as a "precipitant."

Summary

The convulsant possibilities of thiopentone might be suspected, having regard to its near relationship to other strongly convulsant drugs.

The most common phenomena associated with these properties of the drug are: (a) pronatory movements of the arm, sometimes progressing to (b) strong shuddering movements, and even to (c) clonic spasm of other muscles, mostly those associated with respiration, either normal or forced. Tonic spasm of the glottis or of the entire thoracic musculature is not uncommon, and the sphincters also sometimes seem to be involved in the process.

The time factor suggests that no other exciting agent than the drug itself is responsible for their occurrence; but there is a possibility that an inborn convulsive tendency in the patient may predispose to their appearance.

The onset of convulsive phenomena is favoured by absence of premedication, uncombined thiopentone anaesthesia, and repeated thiopentone anaesthesia.

Convulsive signs are most likely to occur in muscular highly trained males leading an open-air life.

They are easily prevented or abated by omnipon-scopolamine premedication and early addition of gas-oxygen in 25% or other suitable mixture.

GRANULOSA-CELL TUMOUR OF OVARY AS ACUTE ABDOMINAL EMERGENCY

BY

A. C. BREWER, F.R.C.S.

Assistant Honorary Surgeon, Liverpool Royal Infirmary

Granulosa-cell tumours of the ovary are usually recognized as a result of their effect on the endometrium, but like other ovarian neoplasms they may give rise to acute surgical complications.

Case Report

A female patient aged 48 years was admitted to hospital complaining of acute abdominal pain of some twelve hours' duration. She had had no previous illnesses. For the last three months she said she had "not been feeling too well," and for the last twelve days she had had a diffuse lower-abdominal pain of a moderately severe nature. There had been no definite colic. During the past five days the pain had become localized in the right iliac fossa and had become more constant; it radiated into both loins. Lying in bed

gave some relief. There had been no nausea and no vomiting. The bowels were regular and micturition normal. The menopause had occurred at the age of 44, and since that date the patient had had no vaginal bleeding. She had two children aged 18 and 12 years, and there had been one miscarriage thirteen months before the birth of her eldest child.

On examination the tongue was moist and had a white fur. The abdomen moved freely on respiration. Tenderness and muscle-guarding were present in the right iliac fossa. Vaginal examination revealed tenderness in both fornices, more marked on the right side. Pain was complained of on moving the cervix. The uterus was slightly increased in size. The condition was diagnosed as subacute appendicitis and operation advised.

A split-muscle incision was made. On opening the peritoneal cavity a considerable quantity of blood was evacuated. The exposure was considered to be unsatisfactory, so a further midline incision was made. About 1 pint (568 ml.) of blood and clot was evacuated from the pelvis. An ovarian neoplasm of moderate size was delivered, with blood clot extruding from two places in its capsule. Salpingo-oophorectomy was performed. The uterus and left ovary appeared to be normal. The patient had an uneventful convalescence.

Comment

The specimen consisted of a tumour measuring 9 x 7 x 5 cm. and having a thick whitish capsule, which in places showed a yellowish colour owing to the tissue deep to it. It had ruptured at two points, and blood clot was protruding from these ruptures.

A portion of Fallopian tube was adherent to the tumour at one point. The cut surface showed a uniform whiteness, but with areas of haemorrhage. On section a dense fibrous capsule resembling ovarian stroma was seen. No follicular elements were present, the tumour consisting of sheets of oval cells lying in a loose stroma rich in blood vessels. In places the cells had an acinar arrangement, but nowhere was there follicular formation. In a few areas there were vacuolated cells resembling Call-Exner bodies. There was a considerable degree of necrosis and interstitial haemorrhage. The appearances were those of a granulosa-cell tumour of the diffuse type.

The granulosa-cell tumour is one of the solid gonadal tumours of the ovary in which the cell elements resemble the granulosa cells of the normal Graafian follicle and has the ability to secrete an oestrogenic hormone. The tumours are almost invariably unilateral, maintain the shape of the ovary within a firm fibrous capsule, and vary in weight from a few grammes to several kilograms. The cut surface is a soft whitish pink with yellow zones, sometimes partly cystic, and occasionally there are areas of haemorrhage. Histologically three main types are recognized according to the degree of glandular-tissue differentiation—follicular, trabecular, and diffuse—and as a general rule the least differentiated tumours show the least hormonal activity. In those tumours with oestrogenic properties the uterine endometrium is of the hyperplastic, non-secretory type with cystic dilatation of the gland tubules. Tumours showing evidence of malignancy are extremely rare. The pathology has been well summarized by Harvey, Dawson, and Innes (1939).

Although haemorrhage into a granulosa-cell tumour of the ovary is common, I cannot find any previous report of a case associated with so severe a degree of haemoperitoneum. The fact that the haemorrhage had been severe enough to burst through a capsule so thick as the one in this case shows the severity of the bleeding. There was no evidence of torsion, a complication that has been reported.

Medical Memoranda

Primary Carcinoma of the External Auditory Meatus

Primary carcinoma of the external auditory meatus is usually considered a rare disease. It is probably not so rare as is generally thought, but can be diagnosed only by biopsy. The early symptoms are aural discomfort, intense and continuous earache, and aural discharge. Local extension is rapid and glandular metastasis rare. Treatment in the early stage is by excision with the diathermy knife, combined in the later stage with radium beam therapy.

ILLUSTRATIVE CASES

Case 1.—Madame Le S., aged 46, was first seen on May 23, 1944, complaining of rapidly increasing deafness in the right ear, together with a slight purulent aural discharge and mild intermittent pain. Her symptoms were of only one month's duration. There was no history of otitis media. Examination revealed a small papillomatous mass deep in the meatus on the postero-superior wall and hiding the drum. The rest of the meatus was the seat of a chronic eczema. A slight fetid purulent discharge was noted. There was a slight diminution in hearing (transmission deafness). Vestibular apparatus was normal. Radiography was negative. A first biopsy gave a doubtful result, but a second, a fortnight later, revealed the presence of a squamous-celled epithelioma. A radical mastoidectomy was performed at the end of June, the whole of the skin of the posterior wall of the meatus being removed. Some inflammatory granulations were found in the middle ear but no neoplastic tissue. A radium needle was applied to the meatus on July 20, being left in position for five days. The patient was discharged on Aug. 12, 1944. The wound healed slowly by granulation. A small papillomatous lesion appeared on the anterior wall of the meatus in January, 1945, and a wide resection of the area was performed with a diathermy knife on Jan. 25. Histologically, the lesion was a squamous-celled epithelioma. In November, 1945, re-examination revealed no recurrence. Epithelialization of the operation cavity was practically complete, but there was some radionecrosis of the tympanic bone, with the presence of a sequestrum (17 months after the radium application).

Case 2.—Madame C., aged 57, was admitted on Feb. 21, 1945, with a history that her left auditory meatus had become blocked by a white hard mass, which was removed by an otologist. She then developed meatal furuncles with intense pain in the ear. This pain had continued unremittingly until her admission. She had been examined as an out-patient in November, 1944, when a small ulcer of the meatus was seen. A fortnight later a sinus in the antero-superior wall was noted, from which pus exuded. Radiography was negative, as was the Wassermann reaction. In spite of local treatment no improvement took place in the symptoms, and some granulations appeared. A biopsy in February showed no signs of neoplasm, and local treatment with silver nitrate was continued. The patient was discharged on March 14, but suppuration and pain continued, and on June 13 a second biopsy revealed a squamous-celled epithelioma. The patient was readmitted on July 3, and a radical mastoidectomy was performed on the 6th. At operation the area of involvement was found to be much more extensive than otoscopy had suggested. The middle ear was filled by a neoplastic mass, and at the level of the roof of the attic the dura was laid bare and covered with very suspicious granulations. A few days later a course of 17 exposures to x rays was begun. A facial palsy appeared on the day after operation, but the pain had already disappeared. The patient still has some secretion from the operation cavity, but pain has not returned and the general condition is satisfactory.

Case 3.—Madame D., aged 49, was admitted for radical mastoidectomy on April 4, 1944. She had suffered from left aural discharge since childhood, without acute symptoms and without vertigo. Hearing on the left side had gradually diminished. She had recently noticed a vague discomfort in the ear. In February, 1944, a doctor had curetted some polyps in her left meatus. On examination she was found to have a left facial palsy and a meatus full of polyps. At operation on April 5, 1944, three large sequestra were removed from the antrum, laying bare the dura. There was osteitis of the wall of the facial canal, and a fungoid mass in the middle ear which could not be removed entirely. The patient was discharged on April 20. On May 15 she was admitted to the Hôpital Claude Bernard for erysipelas. She was transferred to the Hôpital Saint-Antoine on June 13, after having had a large abscess of a cervical gland. Her meatal cavity was discharging freely, and her temperature was 101.1° F. (38.4° C.). Towards the end of June, after sulphonamide and vitamin therapy, her neck condition settled down and her temperature became normal, although the aural discharge persisted. At a meeting of experts on July 4, a biopsy of granulations in

the meatus was performed and revealed a basal-celled epithelioma of the meatus. In spite of the introduction of radium needles and a subsequent course of x-ray therapy the patient had a relapse in March, 1945, with large, painful, fluctuant cervical and submaxillary glands and pyrexia, and she died of exhaustion on April 2, 1945.

Hôpital Saint-Antoine, Paris

A Case of Reversible Papilloedema due to Heart Failure

The following case is sufficiently unusual to make it worthy of record.

CASE REPORT

On Feb. 11, 1947, a man aged 61 was admitted to the Middlesex Hospital under our care with a diagnosis of coal-gas poisoning of two days' duration.

Examination revealed some justification for this view, as he was in a stuporous condition, extremely dyspnoeic, and very cyanosed, the hands and face being a deep blue-plum colour. The blood pressure was 145/95 mm. Hg. Further examination showed that he had marked venous engorgement, a palpable liver, and rales at the base of both lungs. Spectroscopic examination of his blood for abnormal absorption bands was negative. The haemoglobin was 116% and red cells numbered 5,800,000 per c.mm. It was therefore thought that this was a case of left- and right-sided heart failure, probably secondary to long-standing emphysema, bronchitis, and asthma, confirmation of the latter diagnoses being found in a previous history case-sheet giving details of treatment. The blood Wassermann reaction was negative. X-ray examination of the chest suggested that there was some pulmonary arteriosclerosis, the report being as follows: "Bronchitic and emphysematous changes. Prominence of the pulmonary artery, and in the lateral film it appears as dense as the aorta." The electrocardiogram showed right axis deviation.

Dr. D. Evan Bedford reported: "This patient has pulmonary hypertension with dilatation of the pulmonary artery and its branches, but no dilatation of the right ventricle visible by radiology, though there is probably some hypertrophy. There is no evidence in the film of fibrosis of lung. I should regard this as a case of emphysema in which the dyspnoea and cyanosis are mainly pulmonary in origin, not cardiac."

On routine examination of his eyes by one of us (J. B. H.) he was found to have pronounced papilloedema of both disks, the engorged veins being buried at their point of entry into the oedematous disk margin. Mr. A. V. Cooper Stevens confirmed these findings.

The patient was treated by venesection, "cardophylin," and digitalis, and in seven days all signs of heart failure, with the exception of some residual cyanosis of the extremities of the ears and fingers, had disappeared. The papilloedema gradually cleared, and when Mr. A. J. B. Goldsmith examined the fundi on Feb. 18 he reported: "Lens and vitreous clear, right and left. Both fundi show normal disks. The veins are markedly dilated and there is a little arteriosclerosis. There is no papilloedema."

The patient was discharged when better, the blood pressure having now fallen to 100/75 mm. Hg, but he unfortunately relapsed two months later and died in a further attack of cardiac failure in which the bilateral papilloedema was again present. No post-mortem examination was obtained.

Fishberg (1946) states that retinal haemorrhages and papilloedema may occur in right-sided failure due to pulmonary endarteritis. He records that "in one case an excellent response of the symptoms of right ventricular failure to digitalization was accompanied by complete clearing-up of the retinal haemorrhages and papilloedema." The papilloedema is probably due to increased pressure in the venous cranial sinuses interfering with the filtration processes of the arachnoid villi, thus causing a rise in the pressure of the cerebro-spinal fluid.

During the past six years over 500 tons of rose hips have been gathered in Scotland and manufactured into rose-hip syrup. Collectors in 1947 broke all previous records by gathering 144 tons of rose hips as against 113 tons in 1946 and 70 tons in 1945. Credit for this result is due to the Women's Voluntary Services, the Scottish Women's Rural Institutes, and the members of youth organizations and similar bodies.

Reviews

ENCEPHALOGRAPHY

Further Studies in Encephalography. By E. Graeme Robertson, M.D., F.R.C.P., F.R.A.C.P. (Pp. 104; 53 illustrations. £2 2s.) Melbourne and London: Macmillan and Co. 1946.

The author describes methods of ensuring—as far as it is possible—that adequate air replacement may be brought about in all the important channels traversed by the cerebrospinal fluid. Excellent radiographs with explanatory diagrams illustrate the text, and he interprets the pictures well. The theories that he propounds to account for the physical processes occurring in these investigations are interesting though unconvincing—as are the ingenious experiments that are supposed to confirm them. He records some noteworthy data, hitherto disregarded, among the observations on cerebrospinal-fluid pressures. Perhaps it will not be considered out of place here to warn the prospective encephalographer that the manometric pressure in the lumbar theca does not always correspond with the intracranial pressure. The author might have mentioned this, as well as the fact that in some cases even absence of papilloedema does not prove that the intracranial pressure is not raised.

On p. 49 is the comment: "It is reasonable to assume that the maintenance of a constant pressure will diminish the risk of investigation when a tumour is present." How justifiable the performance of encephalography may be in a case of suspected tumour is a matter for serious consideration. But the statement on p. 48 that, "when a patient is confused or drowsy and a cerebral tumour is suspected, the employment of an initial sedative is contraindicated," is not applicable, for few, if any, neurosurgeons would sanction this procedure in any patient in such a clinically deteriorated state. The author's work in encephalography is well known, and the present monograph reveals the high standard characteristic of it. The book should be studied by all who intend to employ this method of visualizing changes within the brain and in the associated cerebrospinal-fluid pathways.

HARVEY JACKSON.

INTRODUCTION TO SYPHILOLOGY

Essentials of Syphilology. By Rudolph H. Kampmeier, M.D. With chapters by Alvin E. Keller, M.D., and J. Cyril Peterson, M.D. Second edition. (Pp. 465; 87 illustrations. 25s.) Oxford: Blackwell Scientific Publications. 1946.

The second edition of Dr. Kampmeier's book differs from the first only in the addition of a short chapter on the intensive treatment of syphilis. The first edition was dated 1944, and the second 1946, but it is clear that the latter was actually compiled in 1944, and the author therefore does not discuss the more modern methods of penicillin therapy, the use of BAL in the treatment of toxic effects, the results of recent investigations into the causation of so-called post-arsphenamine jaundice, and other matters. However, such omissions call for no carping criticism, for the treatment of syphilis, in its early stages at any rate, is changing so constantly that any textbook is out of date as soon as it is published. These remarks should detract very little from a book which is exactly what it is meant to be—a short, concise account of the essentials of syphilology, intended not for the expert but for the student and the practitioner.

This account of syphilis presents it as a protean disease. The author stresses the necessity of careful anamnesis and clinical examination, emphasizes the value of dark-ground examination as the best guide to diagnosis in the early stages, warns against regarding a positive serum reaction as diagnostic in itself, and seeks to arouse practitioners' suspicion of the role syphilis may play in chronic disease. Moreover, he rightly points out that the practitioner has a duty beyond that of merely treating his patient. Syphilis control is even more important to the community than treatment of the individual patient, and every infected person must have contracted it from some other infected person, who should be sought and treated. Almost every chapter starts with a historical note which adds interest for the reader, as do the many summarized case reports which help to conjure up a

mental picture and so aid the memory. Most of the illustrations are excellent; the type is clear and the format above reproach. In addition to the clinical sections, there are chapters on the sociological and epidemiological aspects by two collaborators. Mistakes appear to be rare, but 1.2 g. of arsenoxide per pound of body weight (p. 441) would infallibly land the patient in the post-mortem room.

In spite of these criticisms we confidently recommend this book to the student.

T. E. OSMOND.

RECENT PSYCHO-ANALYSIS

The Yearbook of Psycho-analysis. Volume 2, 1946. Managing Editor, Sandor Lorand. (Pp. 280. 30s.) London: Imago Publishing Co. 1947.

The aim of this series of *Yearbooks*, as set forth by the publishers, is to keep readers acquainted with modern research in the theory and practice of psycho-analysis; but, to judge from the contents, the editors have on this occasion failed to attain that end. The papers collected here, although very readable and in some respects timely, contain little that is new; the volume might indeed have been more appropriately entitled a "Pot-pourri from a Psycho-analytical Garden."

The most useful and illuminating article for the general practitioner is from the pen of Otto Fenichel, whose recent untimely death was a severe blow to psycho-analysis. He classifies the various forms of psychosomatic disorder—a subject that has provoked interest in recent years but given rise to many misconceptions, particularly over treatment. Fenichel was concerned to correct these misconceptions. Helene Deutsch, who has made a close study of women's disorders, contributes a useful article on problems of conception. Kubie and Margolin give an interesting account of the therapeutic role of drugs in the process of repression, dissociation, and synthesis. Their view is that drugs facilitate the recovery of the repressed material and render the personality less vulnerable to disturbance by exposure to it. They do not, however, indicate the many drawbacks to the use of drugs as an adjunct to psycho-analysis.

English writers are well represented by articles from Berg on punishment, Ernest Jones on war conditions, and Flugel on problems of war, peace, and morals. Edward Glover contributes an essay in psycho-analytical biography, the subject being the late David Eder. The reprint of an essay by Freud on "Dostoevsky and Parricide" adds greatly to the attractions of the book.

EDWARD GLOVER.

METAL IN BONE

Metallschädigung bei Osteosynthesen. By R. Nicolé. (Pp. 74; illustrated. 8 francs.) Basle: Benno Schwabe and Co. 1947.

The clinical and experimental researches described in this monograph on metallic hazards in osteosynthesis have led the author to conclusions generally accepted by orthopaedic surgeons to-day. With modern metals, in particular with vitallium and tantalum, any metallosis or toxic effect on the tissues is negligible, but it is a mistake to conclude that no risks remain. If the open reduction and fixation of a fracture are done faultily, so that intermittent or constant bending and shearing strains continue to act across the fracture interval, these will at the same time cause delayed callus formation with poor ossification—even pseudarthrosis—in the bone, loosening of screws, and bending or breaking of the plate, nail, or other elements in the metallic agent used.

The author makes the attractive comparison between the yielding of a plate under such circumstances and the fatigue fracture of a long bone, and indeed the two are very similar apart from the healing reactions in the latter. He postulates that the changes at the sites of stress in the metal are due to "tension corrosion," which differs from ordinary corrosion in that it is precisely restricted to the zones of fatigue in plates and screws, and he cites convincing clinical evidence that this is the case. With his central thesis there must be general agreement. The chief problem in the treatment of fractures and in osteosynthesis (a term which, incidentally, might be more often used in English) is to ensure that the mechanical arrangement of the fragments and the fracture site are physiologically correct until union has occurred.

GYNAECOLOGY

A Textbook of Gynaecology. By James Young, D.S.O., M.D., F.R.C.S.Ed., F.R.C.O.G. Seventh edition. (Pp. 471; 277 illustrations. 30s.) London: A. and C. Black. 1947.

It reflects great credit on Prof. Young that his textbook has been so widely read, and the seventh edition is admirable. The outstanding features are the superb photographs and photomicrographs—indeed, Fig. 119 is as good as any photograph of a wet specimen that we have seen published. The most striking characters of the book are simplicity of expression, clear classification, and sufficient reference to advanced work to whet the appetite of the intelligent student. The chapter on tuberculosis of the generative organs is exceptionally good.

We can criticize only details—for example, Figs. 31 to 35 are repeated as Figs. 96 to 100. The legends are not all satisfactory; Dierk's layer, though beautifully shown in an illustration, is not described. The author emphasizes Hamblen's work, yet his views have been severely criticized, and few workers claim such good results as he. Prof. Young might have said more about the use of androgens in gynaecological therapeutics. In describing the treatment of dysmenorrhoea he does not mention the use of stilboestrol to inhibit ovulation by giving the drug in the early part of the cycle—a method at least as good as giving oestrogens in the few days before menstruation starts. His account of the endocrines in relation to amenorrhoea is perhaps not adequate to modern needs, and he might have described more fully the adrenogenital syndrome, Cushing's syndrome, and panhypopituitarism. Prof. Young will be congratulated by all gynaecologists on this edition, and we can confidently recommend it to both students and general practitioners.

WILFRED SHAW.

HEALTH SERVICES

Municipal Health Services. By Norman Wilson, M.A., Dipl.P.A. (Pp. 178. 7s. 6d.) The New Town and County Hall Series. London: George Allen and Unwin, Ltd.

This small book of 178 pages is the third volume in "The New Town and County Hall Series." The author's aim is to discuss what are often called personal health services, and in Part I he describes the usual practice of local authorities with regard to maternity and child welfare, the health of the school child, tuberculosis and its treatment, the control of communicable diseases, the care of the mentally afflicted, general hospitals, poor law, and other services. A section of the book is devoted to "The Administrative Machinery," and he gives an account here of the powers and duties of the Ministries of Health and of Education and of the various types of local authorities.

Part III is entitled "A National Health Service" and is most disappointing. In the foreword the author states that the Government's proposals for a national health service had not been made public when the book was going through the press, but he quotes the Government's White Paper on the subject on p. 165, though giving no guidance to the new scheme. Although Part III begins with a section on "National Health Insurance" the author does not refer to the very important White Papers on social insurance (1944) or to the National Insurance Act, 1946, which make such radical changes that discussion of them should not be omitted from a book of this kind. Most of the information contained in this book has been recorded previously, and it is a pity that a volume in such a series is not more up to date.

J. M. MACKINTOSH.

The late Sir Frederick Hobday (1869–1939) was a master of the craft of surgery and of the art of eliciting his patient's trust; an innate tenderness flowed through his fingers. By his qualities and his book, *Hobday's Surgical Diseases of the Dog and Cat*, of which the first edition was published in 1900, Hobday raised the scope and standard of operative surgery on the smaller animals. The book's merits are in its descriptions and illustrations of the operative and after-care techniques, which, for the fifth edition (Baillière, Tindall and Cox, 1947; 21s.), have been brought up to date by Hobday's able deputy, Prof. James McCune, of the Royal Veterinary College. The book's defect is its account of pathology, which needs a thorough revision.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Brompton Hospital Reports. Vol. XV. 1946. (Pp. 192. 10s.) Aldershot: Research Department of the Hospital. 1946. Includes articles on various aspects of chest disease.

Tuberkulose-Probleme im Kanton Zürich. Compiled by P. Press and M. Brunner. (Pp. 125. 10.80 Swiss francs.) Basle: S. Karger. 1947.

A monograph on tuberculosis in Zurich.

Detoxication Mechanisms. By R. Tecwyn Williams, Ph.D., D.Sc. (Pp. 288. 25s.) London: Chapman and Hall, Ltd. 1947. An account of the metabolism of a number of organic substances used in medicine or industry.

La Psicosis Pelagrosa. By Dr. Bartolomé Llopi. (Pp. 206. No price.) Barcelona: Editorial Científico Médica. 1946.

An account of the mental changes that may occur in pellagra.

Chronic Structural Low Backache due to Low-back Structural Derangement. By R. A. Roberts, B.Sc., M.B., Ch.B., D.M.R.E. (Pp. 105. 45s.) London: H. K. Lewis. 1947.

Discusses structural vertebral defects causing backache, their diagnosis and treatment.

The Treasury of Human Inheritance. By Julia Bell, M.A., F.R.C.P. Vol. IV. Part V. Edited by L. S. Penrose, M.D. (Pp. 68. 21s.) Cambridge: University Press. 1947.

An analysis of pedigrees of cases of dystrophia myotonica and allied disorders.

Uncle Xavier. By D. H. Landels. (Pp. 192. 9s. 6d.) London: Hurst and Blackett.

A novel.

Pharmacology, Therapeutics, and Prescription Writing. By Walter Arthur Bastedo, Ph.G., M.D., F.A.C.P. 5th ed. (Pp. 840. 42s.) London and Philadelphia: W. B. Saunders Co. 1947.

This textbook for students and practitioners has been brought up to date and includes new material on BAL, folic acid, anticoagulants, and antibiotics.

Diseases of the Nose and Throat. By Charles J. Imperatori, M.D., F.A.C.S., and Herman J. Burman, M.D., F.A.C.S. 3rd ed. (Pp. 576. 72s.) London: J. B. Lippincott Co. 1947.

This edition includes new material on vitamin deficiencies, chemotherapy, and antibiotics.

Uterine Contractility in Pregnancy. By Douglas P. Murphy, M.D., F.A.C.S. (Pp. 134. 30s.) London: J. B. Lippincott Co. 1947.

A monograph based on uterine contractions in 1,200 pregnant women.

A Textbook of Clinical Neurology. By Israel S. Wechsler, M.D. 6th ed. (Pp. 829. 42s.) London and Philadelphia: W. B. Saunders Co. 1947.

A textbook for student and practitioner.

Selected Papers from the Royal Cancer Hospital (Free) and the Chester Beatty Research Institute. Vol. IV. (Pp. 331. 16s.) London: 1943–4.

Nicolans Pol Doktor 1494. By Max H. Fisch. (Pp. 235. \$7.50.) New York: Herbert Reichner. 1947.

Biographical and bibliographical details, with a translation of Pol's tract on guaiac.

Sir Frederick Banting. By Lloyd Stevenson, M.D. 2nd ed. (Pp. 446. 25s.) London: William Heinemann. 1947.

A biography, with many extracts from Banting's letters.

Bad Hofgastein. By O. E. Zimmermann. (Pp. 64. 4.50 Swiss francs.) Vienna: Springer-Verlag. 1947.

A guide to the spa for medical men. In German.

Terapia Endoarteriosa. By E. Malan and G. Enria. (Pp. 124. 900 lire.) Turin: Edizioni Minerva Medica S.A. 1947.

A monograph on treatment by intra-arterial injection of drugs.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JANUARY 10 1948

ARE WE CONVINCED?

The medical profession has lost little time in making an effective rejoinder to Mr. Bevan's reply to the Negotiating Committee. Our correspondence columns show that doctors are now fully alive to the implications of the National Health Service Act and becoming firm in their resolve to say "No" to a Minister whose method of negotiation is to alternate blandishments with threats in his successful attempt to avoid discussing those matters which the Negotiating Committee consider to be fundamental points of disagreement between the medical profession and the Ministry of Health. The Committee which met the Minister on Dec. 2 and 3 were certainly treated to a brilliant exhibition of dialectical skill. But this was not really the purpose of the meeting with the Minister. The purpose was negotiation, and Mr. Bevan once more proved that his interpretation of the meaning of this word differs from that which is usually accepted.

The expression of opinion in our correspondence columns against service under the Act in its present form received resounding support in two large and important meetings held last week in Wimbledon and B.M.A. House, addressed respectively by Dr. H. Guy Dain, the Chairman of Council, and Dr. Charles Hill, the Secretary of the B.M.A. Loud applause greeted Dr. Dain when he said, "We are not prepared to be in a salaried position in which the interference of a State department may come between us and the interests of our patients. With a salary even as small as £300 a year we shall begin to experience control." After a thorough and objective analysis of the Minister's reply Dr. Hill asked, "What does it all add up to?" And he went on:

"There is one criterion by which as a profession we can measure these matters. It is not, I hope, a financial criterion. It is whether these proposals do or do not bring us closer to a whole-time salaried service of the State. That is the crucial issue, and on that issue we can command the support of the overwhelming majority of our profession."

The meeting was the largest that had ever assembled in B.M.A. House, and it listened with close attention to Dr. Hill's reasoned exposition of the case for over an hour. The loud applause which greeted the statement quoted was, therefore, all the more impressive. The Act, Dr. Hill observed, was the first step to the fulfilment of the Socialist programme for a whole-time State Medical Service. The general practitioner in the proposed new Service will be unable to begin work without the permission of a Committee in Whitehall; he will be paid in part by salary, and at any time the Minister by regulation can decree that payment shall be wholly by salary; he will no longer own the goodwill of his practice and will, therefore, lose the

plot of ground which in a free society enables him to preserve his freedom as an individual. The consultant and the specialist will have to work in hospitals owned by the Minister of Health, who can under the terms and definitions of the Act at any time take over any institution in which sick persons are being treated. The sign-posts all point in one direction—control of the medical profession by the State. To make quite sure that the reins of control shall be firmly in one pair of hands the Minister insists upon the appointment by him of the Chairmen of various administrative committees down to the Local Executive Council. On Monday this week he sent a letter to the Secretary of the Negotiating Committee asking the B.M.A. to propose names for the members of the Medical Practices Committee. This letter is another indication that the Minister has banged the door in the face of the profession and is determined to go on with his Act in spite of the fact that he has failed to secure what he has stated to be indispensable—namely, the co-operation of the doctors of this country. And it is for the doctors of this country to decide whether a medical service begun in this way and initiated by a Minister who has shown himself contemptuously indifferent to reasoned arguments shall come into operation in July this year.

One thing is certain, and that is that the Act cannot come into operation if the large majority of medical men and women stand firmly outside the new Service on July 5. The size of this majority will depend upon the strength of the conviction held that a State Medical Service will be harmful to medicine and therefore to the public which the profession of medicine serves. If the profession is so convinced, then it should need but a modicum of courage to hold fast to that conviction. The medical profession is in a strong position and should be more conscious of that fact. Its services are indispensable to the welfare of the community and will, of course, never be withheld. But it can determine the conditions of its work and insist upon maintaining a framework of liberty and freedom which at the same time includes order. That framework of freedom and liberty is not present in the National Health Service Act of 1946, and the Minister has refused to modify its structure. Some medical men have argued that to oppose the Act is to oppose the will of the people as expressed through Parliament. But as Dr. Hill put it in his speech last week: "The Minister has told us of our right as individuals and our right collectively to determine our attitude to this Service. We are within our rights in saying 'No.'"

Mr. Bevan has refused the right of practitioners to appeal to the Courts against the decision of the Minister to remove him from the Public Service—a Public Service which is to include every man, woman, and child in the country. This right of appeal has been included in the Health Service Bill of Northern Ireland. This is "the new despotism"—the execution of justice by the head of an administrative department of State. He refuses to amend Section 35 in spite of the fact that no one knows exactly what it means. He calmly tells the profession that if it does not mean what he thinks it means he will, after the matter has been submitted to the Courts in the future by individual practitioners, amend it in order to make it mean what he thinks

it means. This attitude borders on the irresponsible. Until this Section is amended, as in due course it will have to be, no practitioner in partnership will know how he stands if he enters the Service on the appointed day. The Minister refuses to listen to the Negotiating Committee's objection to the basic salary. It should be clear that no objection has been raised to the use of a salary to attract men into difficult or undesirable areas or even to help the young man entering practice for the first time. During the debate on the third reading of the National Health Service Bill in the House of Lords,¹ the Government was defeated on the basic salary issue by an amendment proposed by Lord Llewellyn that remuneration should be by capitation. The real reason for basic salary was given away by the Lord Chancellor when he said: "No one could have been, as I have been, Minister of National Insurance, without realizing that the success or failure of all our schemes depends in a very large measure on our getting satisfactory certification." As we said then, the reason for the basic salary is to control certification. The reason for it is distrust of the doctor. Because some doctors have been lax in certification—and the Lord Chancellor admitted that he had only come across a few instances—all doctors are to be treated as if they were offenders. The Lord Chancellor gave another warning which it is well to take to heart: "If you had abolished this per capita payment altogether and made it a straight out-and-out salary, of course that temptation would have gone." Once the National Health Service Act in its present form is in operation the Lord Chancellor's "out-and-out salary" will be introduced to remove any temptation medical men may have to act as free and responsible individuals.

The analysis made by the Negotiating Committee and again by Dr. Hill last week shows how unsubstantial is the Minister's case for abolishing sale and purchase of practices, for the payment of a basic salary, and for the distribution of doctors through the machinery of the Local Executive Councils and the Medical Practices Committee. The Minister admits that there will be very few areas in which there will be difficulty in providing doctors. Why, therefore, does he set up this expensive and cumbersome machinery for distributing doctors? One reason he has given for abolishing sale and purchase of practices is to secure the even distribution of medical men throughout the country. But if there are so few areas which offer difficulty why again make such expensive and sweeping proposals to deal with such a small problem? On another occasion, it should be recalled, the Minister referred to the sale and purchase of practices as "an intrinsic evil." To Mr. Bevan, no doubt, all private ownership is an intrinsic evil; we believe monopoly State ownership to be a greater evil. There is even a hint in the Minister's reply that he may regard the ownership of the doctors' house as an intrinsic evil when he makes his curious proposal that the Local Executive Council may be able to buy a house for the incoming doctor. Or this may have been another attempt by the Minister to put a favourable gloss on the finances of the medical man in the proposed Health Service. Many men, it would seem, have been misled by

his statements into believing that general practitioners in the Public Service of the future will all be receiving an income of about £3,300. In fact, as Dr. Hill points out, the average gross remuneration per year for the general practitioner will be £1,816. The good general practitioner who by his efforts can to-day build up a successful practice will suffer financially under Mr. Bevan's proposals for remuneration. The practitioner whose practice is below the average may benefit financially under Mr. Bevan's proposals. These proposals in effect are part and parcel of the levelling-down process to which this country is being subjected by the present Government on the curiously unbiological thesis that all men are equal. One result of the National Health Service Act is already visible in the big increase in the numbers of those seeking to take special diplomas and in particular the M.R.C.P. The young medical man of to-day who believes that his ability may be above the average is doing all he can to avoid going into general practice under Mr. Bevan's Act. He is, therefore, trying his hardest to secure diplomas that will enable him to practise as a specialist or consultant. Although he will be as much a State servant in the Consultant Service as in the General Practice Service he does at least hope to escape the economic levelling down to which Mr. Bevan's proposals subject the general practitioner of the future.

The Representative Body is holding a special meeting whilst this *Journal* is in the press. We believe that this meeting will offer still another proof that Mr. Bevan has failed to secure the co-operation of the majority of the medical profession in the launching of his new Service. We believe, too, that the plebiscite to be taken on Jan. 31 will show that the majority of the medical men and women of this country will refuse to take service under the Act in its present form. Mr. Bevan still has time to amend the National Health Service Act so as to secure the willing co-operation of the medical profession in making it a success. If he does not seize his chance to act in a statesmanlike fashion then he will put the health services of this country into jeopardy, embitter the relationship between the doctor and the State, and sow among doctors themselves discords that will echo for years to come.

BRITISH TRANSPORT MEDICAL SERVICES

The fourth and largest experiment in nationalization by the present Government was formally launched on Jan. 1, when the British Transport Commission came into being.¹ Throughout the nineteenth century the Houses of Parliament based their railway policy on the need for keeping competition alive.² The 1914-18 war brought this policy to an end and led indeed to its complete reversal in the Railways Act of 1921, which forcibly amalgamated practically all the railways into the familiar group of four. The Transport Act of 1947 unifies these into one body with the London Passenger Transport Board. In 1825 when the Stockton and Darlington Railway began to carry passengers there were 26 miles of track. The British Transport Commission takes over 52,000 miles of railway with 20,000 locomotives and 45,000 passenger vehicles. It will employ some 700,000 people. Government spokesmen have

¹ *The Times*, Jan. 1, 1948, p. 2, col. 1.

referred to "a very poor bag of physical assets" with all equipment badly worn as the result of intensive wartime usage. The extent to which the railways are in need of new rolling stock is well known to the most infrequent passenger. Public transport whether by train, bus, or tube has a bearing on public health, and this may be the right time to urge upon the newly created British Transport Commission and its various Executives the need for bearing in mind the health as well as the safety of its customers.

Pulvertaft¹ pointed out recently that the maximum risk of air-borne infection, especially through droplets, is present when human beings are closely crowded together, as they are under modern transport conditions. At least twice a day every city worker is exposed to conditions "where no known method of air sterilization could possibly operate." This observation is "probably right,"² but that is not to say that modern railway coaches could not be so designed as to minimize these twice-daily hazards. One remedy has already been suggested.³ American railway coaches provide comfortable high-backed adjustable seats which all face the same way. This makes it difficult for even the most garrulous passengers to project their infected droplets at each other. American coaches are of the one-compartment variety, air-conditioned and warmed, perhaps over-warmed by our standards, and with double doors and small vestibules at each end so that arrivals and departures are not commemorated by blasts of cold air.⁴ An obvious question which it should be possible to answer is whether small herds in small box-compartments are less or more at risk than larger herds in larger coaches. It is the fact that some of our railway coaches were designed sixty or more years ago for a public not given to much travelling and in mortal dread of fresh air.⁵

In this country trains are trains and rarely undergo the kind of metamorphosis which became familiar during the war years, when there were few injured men who did not at some time experience the mixed blessings of a hospital train with its M.O. in charge, attached Q.A.I.M.N.S., and occasional V.A.D.s. Less romantic were the railway coaches which became large-scale disinfestors when the line at El Alamein had been held after the long retreat but typhus presented a problem almost as threatening as the Afrika Corps. Disinfestors are, of course, regularly used by all British railways, but these are not hurriedly modified coaches such as had to be used in Egypt. Long before the war the French had converted two coaches into a mobile radiological unit, and recently a new x-ray train was completed at Le Landy, just outside Paris.⁶ It is now in use in the Northern Region, and since it is equipped to deal with 600 people a day it should be possible to examine radiologically every member of the staff of the Northern Region of the French Railway, and their families, once a year. It should be recalled in this connexion that the French Railway Medical Service is responsible for treatment as well as for examination and diagnosis.

In this country mobile examination coaches are employed on a limited scale, but here railway medical officers, like

other industrial medical officers, have been little concerned with the treatment normally given by general practitioners. They co-operate closely with general practitioners but act as a rule in an advisory capacity and particularly on problems of rehabilitation. Each of the main-line railways has employed full-time medical officers for many years—in the case of the Great Western Railway for over 40 years. The London Passenger Transport Board, which was created only in 1933, appointed its first full-time medical officer in 1934. In the case of the main-line railways and of the London Transport, medical services were provided by full-time officers and a number of general practitioners with special railway experience giving part-time services. These services were designed to meet certain special and obvious needs. The over-riding considerations have always been and will continue to be the public safety and the well-being of the railway staff. Out of this there arises the question of fitness for entry into the service, with particular reference to tests of vision, including colour vision. Signalmen and engine drivers, for example, must have normal colour vision. The other work in which transport medical officers were soon involved was in connexion with Workmen's Compensation. It is expected that they will be relieved of much of their responsibility in this connexion when the National Insurance (Industrial Injuries) Act of 1946 comes into operation in July. The changes which will be brought about by this Act were commented on in these columns last year.⁷

Inevitably these medical officers, of whom there are now 30, soon became concerned with industrial medicine in its broader sense. So far as is known at present there are few occupational diseases peculiar to transport workers in anything like the way that there are well-defined occupational hazards in connexion with mining and other industries. There are, of course, some special injuries such as those in shunting accidents. It has also been alleged often enough that peptic ulcer is commoner in transport workers than in the general population, but no convincing evidence has yet been produced on this point.

The Transport Act will lead to a closer integration between what were the four main-line railways and London Transport. It should be recorded, however, that in the past few years there has been a close liaison between medical officers in these groups, discussing particularly such subjects as standards of vision, which previously varied to some extent. There will obviously be greater scope under the new arrangements, for instance, for standardizing records of sickness absence on a scale which may make it possible in future to answer the kind of questions that have been asked about the incidence of peptic ulcer and other conditions in special groups of transport workers.

For some years now the main-line railways and London Transport have had consultant medical advisers and have availed themselves of their specialized knowledge on different problems, but there has not so far been a formal medical research side of the transport medical services. Individual problems have been dealt with as they arose, with,

where necessary, the assistance and guidance of specialist advisers. We understand that London Transport made an informal approach to Prof. Le Gros Clark and his colleagues at Oxford on the problem of fitting the bus to the bus driver. It will be recalled that Prof. Le Gros Clark was responsible for much of the wartime work on this subject, some of which was reviewed in our columns.¹⁰ This side of industrial health—what may be termed the physiological approach—is obviously one that will develop in the future.

Meanwhile the transport medical services can look back upon a useful record of service to the community and to railwaymen. The G.W.R. Medical Fund Hospital at Swindon, established in 1871, is well known, as are some of the railway convalescent homes. The L.M.S. Railway was early in the field of rehabilitation, establishing before the war a small centre at Crewe for what was then termed the "reconditioning" of injured workers.¹¹ The Transport Act of 1947 should allow of a closer integration of these medical services and a steady development in industrial health along the lines which are now becoming familiar and which involve job analysis, personnel selection, the provision of first-aid services, and the closer fitting of machines to men. It is unlikely that the present changes will have any immediate effect on railwaymen, on the travelling public, or on the transport medical services, but there are clearly opportunities for future development in which it is important that the health of the passenger should be regarded as second only to his safety in importance. Integrated records over a number of years may make it possible to answer some of the questions that have been asked in the past about particular conditions affecting transport workers. For example, is it true that railway officials in this country show lower mortality rates than the general population, except for diabetes and appendicitis,¹² and if so why? How many upper respiratory infections are contracted on the 8.10 every morning, and is there any reason why this number should not be diminished by investigation and more careful design of railway carriages? For many years it has been suggested that the railways should be nationalized. Now they are nationalized, and it remains to be seen what the future will hold for the travelling public, for transport workers, and for the medical services of British transport.

MYOCARDITIS

Owing largely to the exertions of McKenzie, Lewis, Parkinson, and others, abuse of the term myocarditis has been more or less corrected. Apart from rheumatic and diphtheritic carditis the condition is rarely recognized to-day. The reaction to misuse of the term may, however, have gone too far, as we are reminded by Ira Gore.¹ Auricular fibrillation or flutter, sudden death from ventricular fibrillation, partial heart-block, inverted T waves in the electrocardiogram, and congestive heart failure bear witness to the reality of carditis associated with lobar pneumonia.

Repeated reports on Fiedler's or isolated myoearditis have testified to the existence of a form of heart disease characterized by focal necrosis, focal cellular reaction, and late focal fibrosis. Gore points out that a similar pathological picture may be found subsequent to streptococcal sore throat or the common cold, and should not then be identified with rheumatic carditis. Focal hyaline or granular necrosis with round-cell infiltration² has been demonstrated in many fatal cases of scarlet fever. The occurrence of pulmonary oedema, rise of the venous pressure, and inversion of T waves in acute nephritis and in toxæmia of pregnancy³ is not satisfactorily explained by left ventricular failure secondary to acute hypertension; for in some of these cases the blood pressure is not nearly high enough to embarrass a healthy heart. The literature is studded with examples of carditis based on clinical, electrocardiographic, and post-mortem evidence in a host of infectious diseases, and it is time their significance was properly assessed. In this respect focal hyaline necrosis produced by digitalis,⁴ by acetylcholine, and by vagal stimulation⁵ should not be forgotten. Toxic carditis from other drugs may occur. Emetine, once regarded as particularly dangerous, was more or less exonerated in the last war, at all events in therapeutic doses. Sulphonamide hypersensitivity, however, provides an example.

Clinically, toxic carditis is not easy to recognize unless there are changes of rhythm or unless the condition is so advanced as to cause heart failure or sudden death. Other signs and symptoms, particularly tachycardia, are difficult to distinguish from those due to emotional disturbance. The electrocardiograph, however, provides a valuable diagnostic aid, and significant changes should be treated with respect.

CHLOROPHYLL AS A BIOGENIC AGENT

The word "biogenic" is employed by some American workers to describe substances which appear to accelerate the healing of wounds. In the past it has been claimed that extracts of heart muscle and of embryonic tissues increased the rate of healing of ulcers and wounds; but controlled experiment has been difficult, and where controls have been devised the effect of these extracts on epithelial growth has been shown to be inconsiderable or even inhibitory. It is now suggested that water-soluble derivatives of chlorophyll exercise a complex but beneficial influence upon the healing of wounds.

Numerous pharmacological effects have been attributed to chlorophyll. Gordonoff and Hosokawa¹ found that an exhausted muscle-nerve preparation will contract when chlorophyll is applied to it. Other authors²⁻⁶ have drawn attention to the chemical relationship between chlorophyll and haemoglobin and have suggested that chlorophyll stimulates erythrocyte formation and the elaboration of haemoglobin. Koenigsfeld⁹ and Rydin¹⁰ observed that chlorophyll increases the metabolic rate of tissues. Working in Burgi's laboratory, Rollet¹¹ reported that extracts of plant pigment stimulated tissue growth, and Gordonoff

and Ludwig¹² showed that such extracts increase the rate of growth of fibroblasts *in vitro*. Smith and Sano¹³ confirmed this finding and demonstrated that it was not due to the presence of vitamins B and C; Smith and Livingston¹⁴ claimed that the same effect could be obtained by applying chlorophyll to wounds in man.

Bowers¹⁵ now reports that after operations for pilonidal cyst, anal fistula, and empyema, and also in gunshot wounds, fungating tumours, burns, and certain ulcers, healing appeared to be accelerated after the application of water-soluble derivatives of chlorophyll. There was more rapid healing, prompt deodorization, and the growth of saprophytic secondary invaders was inhibited. The flow of pus was lessened when chlorophyll preparations were applied in cases with nasal suppuration and in certain inflammations of the eye. Bowers admits the difficulty of obtaining satisfactory controls in these conditions, but supports his own observations by the unanimous clinical impressions of more than thirty-five colleagues.

ALLERGY AND THE EYE

The part played by sensitization in diseases of the eye has been studied experimentally and clinically for many years. Many disorders of the eye are now attributed to bacterial sensitization and to allergic reactions to foods, inhalants, and contactants. Cooke¹ classifies allergic reactions of the eye into the following types: artificially induced, spontaneously occurring immediate weal, dermatitis, and bacterial sensitization. Walker² found that of 17,000 cases a year attending the Oxford Eye Hospital 340 (2%) had been satisfactorily proved to be allergic both by skin tests and by removing the offending allergens and then causing the symptoms to reappear on further contact. Of these 340 cases 55% suffered from conjunctivitis, 36% from migraine, 2.9% from keratitis, 3% from iritis and iridocyclitis, and 0.1% from cataract. However, ophthalmologists and allergists do not all agree on what they mean by allergy.

Duggan³ defines allergy to include all those aseptic or abacterial lesions in which the common element of the basic morbid process is either increased capillary permeability or excessive contraction of smooth muscle in the arterioles or both. He develops the thesis that an allergic disorder of the ocular tissues can be interpreted as a manifestation of localized vascular dysfunction. Acute congestive glaucoma, herpes zoster ophthalmicus, paralysis of ocular muscles, vascular disturbances of the retina, acute optic and retrobulbar neuritis, uveitis, sympathetic ophthalmia, serous retinopathy, and episcleritis are all discussed on this basis. Treatment is by vasodilators. Duggan has been treating many of these conditions with vasodilators for some ten years with beneficial results. In the article referred to he describes four illustrative cases of herpes zoster ophthalmicus and seven cases of paresis of ocular muscles treated by vasodilators. As he admits, controls are difficult to obtain, but the times taken to cure seem to be much shorter than by the more usual methods of treatment. A man of 47 with herpes zoster ophthalmicus, keratitis profunda, and cyclitis was clinically cured in thirteen days. A woman of 34 with herpes of the left side of the forehead and a vesicle and marked oedema of the left upper lid, who had severe pain unrelieved for five days, was clinically cured in five days. The other two cases of herpes were in a girl aged 9 and a man of 23, both of whom had mild herpetic iritis; both were clinically cured in four days. In previous cases, summaries of which he records, marked benefit was obtained in episcleritis and scleritis, serous retinopathy, acute exuda-

tive choroiditis, iritis and iridocyclitis, and acute retrobulbar neuritis. His vasodilator therapy consists in intravenous sodium nitrite, 0.1 g. daily, with erythrityl tetranitrate, 30 mg. once or twice a day. Nicotinic acid, 100 mg. t.d.s., with erythrityl tetranitrate was used in one case.

BRONCHIO-CONSTRICTION AND ANTI-HISTAMINE DRUGS

The ability of antihistamine substances, sympathetico-mimetic amines, and other drugs to counteract histamine broncho-constriction in animals has received widespread attention, but until recently such tests have not been applied to human subjects because of failure to demonstrate significant broncho-constriction after doses of histamine that could safely be administered. Curry⁴ has recently studied the effect of histamine on the respiratory tract in man. In 10 normal subjects and in 10 who had a history of severe allergic disturbances, including 5 with a history of asthma but free from symptoms at the time, no notable reduction of the vital capacity was observed following the administration of histamine intramuscularly or intravenously. In 8 out of 9 patients with active asthma and varying degrees of chronic bronchitis and emphysema, broncho-constriction, as shown by a reduction in the vital capacity, was noted after the administration of histamine. The vital capacity was reduced from 9% to 33% after an intramuscular injection of histamine, the maximum effect appearing 2 to 3 minutes after the injection with a return to normal in 20 to 30 minutes. After intravenous injection the vital capacity was reduced to between 27% and 71%, the maximum effect being observed usually 30 seconds after the injection with a return to normal in 5 to 10 minutes. The effective dose was between 0.08 mg. and 0.2 mg. of histamine base when given intramuscularly and between 0.02 and 0.03 mg. intravenously. Broncho-constriction in these patients could also be produced on administering histamine by nebulization or sublingually. The sensitivity to histamine varied from person to person, and in the same individual it varied with the severity of the asthmatic symptoms. However, during any one period of study the repeated injection of the same quantities of histamine by the same route brought about a similar degree of broncho-constriction.

In a further series of experiments on these histamine-sensitive patients Curry² investigated the antihistamine effects of various drugs. "Benadryl," 30 mg. in 50 ml. of normal saline, given intravenously before the injection of histamine, provided marked and rapid protection against the systemic and broncho-constrictive effects of parenteral histamine. Pyrabenzamine, 50 mg. orally, gave a slow and irregular protection, while its effect in different subjects varied, one showing no protection. Adrenaline intramuscularly and "aminophyllin" intravenously produced rapid and complete protection, while with ephedrine intramuscularly it was two hours before the protective action became complete. Atropine gave only partial protection. This "tracheo-bronchial reaction" to histamine in a sensitive subject provides a convenient means of assaying the effectiveness of antihistamine and allied drugs in man and is of special interest in view of the recent development of the antihistamine group of drugs.

Dr. C. M. Fletcher, F.R.C.P., will deliver the Goulstonian Lectures before the Royal College of Physicians of London (Pall Mall East, S.W.) on Tuesday and Thursday, Jan. 13 and 15, at 5 p.m. His subject is "Pneumoconiosis of Coal Miners."

THE TIME FOR ACTION

DR. DAIN'S ADDRESS TO SURREY PRACTITIONERS

Wimbledon Town Hall was crowded on Sunday afternoon, Jan. 4, for a meeting of members of the profession from all parts of the county of Surrey which was addressed by Dr. H. Guy Dain, Chairman of Council of the Association. The chair was taken by Wing Commander H. M. Stanley Turner, who was supported on the platform by members of the Branch Council. The success of the meeting was largely due to the excellent work put in by Dr. T. W. Morgan and Dr. J. W. Starkey, honorary secretary of the Branch.

The Chairman, in introducing Dr. Dain, said that this was a meeting of doctors called irrespective of membership of the B.M.A. or any other body. They welcomed the statement on the Minister's reply which the Council of the B.M.A. had published (Dec. 27, p. 1046). It confirmed the views which many of them had held from the beginning that what was intended by the Government was the subjection of the private medical practitioner to the will of the politicians on the pretext of improving the health of the community. This was to be achieved by the conversion of the profession into a class of Civil Servants controlled and supervised from above. Some of them had been present at a meeting at Guildford recently at which German doctors testified that Hitler at the very inception of the Nazi regime imposed almost the same conditions on the profession in Germany.

They had waited long and patiently for some directive from the B.M.A., and it seemed, for a time, in vain. But the result of the recent discussions now published showed that there was no longer any room for doubt or misgiving. The irresistible force was about to encounter the immovable obstacle. In Surrey they were solidly behind the B.M.A. A member of the Labour Party had told him that the Minister could rely on sufficient disunity in their ranks to be sure of getting what he needed, at any rate in the industrial areas, by the appointed day. The Minister might get a surprise. Control and regimentation were foreign to this country and to the profession. Only by conceding the fair and reasonable conditions asked for by the B.M.A. in the name of a free profession would the Minister get a helpful and co-operative service, and, what should appeal to him, a service without labour troubles.

Meetings with the Minister

Dr. H. Guy Dain, who was received with cheers, said: We have been talking for a long time and we are now faced with the prospect of action. The Minister has had it in his mind from the beginning that he would succeed in dividing us. I met him at various social functions and he never failed to tell me that the medical profession was divided. When he said it the first time I thought he was just being funny; the second time I attributed it to mere repetition; but when he said it the third time I decided that he was afraid we were not so divided as he liked to suggest.

We met the Minister in February, having forced his hand to the extent that he agreed to discussions with the possibility that amendment might follow. We determined not to enter into discussions on regulations but only on the Act as a whole, and he accepted that decision, though, as we think now, with no real intention of amendment. We set up committees and examined the Act from end to end according to the various types of work on which the profession is engaged. The more closely we studied the Act the more convinced we were of the rectitude of our principles and the necessity for their implementation before we could accept service. A close examination of the Act has made it more and more obvious to those who have taken part that it is essential to obtain amendment before service can be entered upon.

Something must be said about the interviews with the Minister himself at the end of the detailed discussions. His tone was very different from what might be inferred from his written reply. In discussing the general practitioner service he was just rude, blustering, and threatening. He left that meeting, no doubt, satisfied that he had given nothing away, and for my part I went away delighted because, not having conceded any principles, he had not offered us any small amendments

which would have made our position more difficult and the issue less clear-cut. But when next morning we discussed with him the position of the consultants he was smooth and amiable. He said that he realized that there must be a fourth class of hospital patients, that in addition to those who have hospital services free, those who paid for hospital amenities but not for medical service, and those who paid the full cost of maintenance and a professional fee the amount of which was to be determined by the Minister, there must be a fourth class consisting of those who paid full hospital maintenance and such fee as the consultant thought the patients could afford.

Quite obviously he had the intention of placating the consultant side of the profession while being extremely rude to the general practitioner side. For my part I hope that consultants and specialists as well as general practitioners will have nothing to do with the Service until the proper amendments have been put into the Act. (Hear, hear.) In the document before us he has asked those concerned to co-operate with him and see how it works, and if it is found that things require amendment they can be amended afterward. "Will you walk into my parlour," said the spider to the fly.

Remuneration

I want to take you through some parts of the Minister's statement. First, remuneration. It is said by some people to be a very attractive offer, by others to be not as attractive as it seems. Speaking as a general practitioner I had always supposed that if all my better-off patients were to be absorbed into the National Health Service I should have a much higher capitation fee than obtains in respect of people with limited incomes under National Health Insurance. Any capitation fee of less than £1 is likely to leave me worse off than at present.

This 18s. offer embodies two or three things against which we have set our face all along. One is the sliding capitation fee. As the result of the £300 basic salary, the greater number of doctors who come in, the smaller the fee. We must have a fixed capitation fee. We shall require also that wherever capitation fee is fixed the mileage fund must be outside. That is a separate consideration. Mileage does not apply to us all. It applies to certain doctors in certain areas, and it is not proper to allow it to affect the capitation fee applicable to the whole country. Incidentally I do not think the amount set aside from the pool will recompense rural doctors for the additional time their work takes as compared with the town doctor.

In a document which you will receive shortly you will find the capitation fee analysed carefully, and it will tell you exactly what you will be paid in different circumstances. The Minister states that with the maximum number on your list you would get £3,332 a year. This would apply only to very few people. Under N.H.I., which includes half the population, the average number on the list is 1,000; with the whole population included it may be taken at 2,000, so that instead of a gross income of £3,332 the practitioner would on average get a gross income of £1,816, or about £1,200 net. That makes the offer not nearly so attractive as it appears when it is stated that instead of the present 15s. 6d. for insured patients the practitioner will get 18s.

The Minister makes great play with the fact that practitioners will earn outside money. But when everybody is provided for there will not be so much from this source. The public assistance doctor will disappear, the police surgeon and the police office doctor will find their work contracted, and there will not be much opportunity in many areas to earn money outside the National Health Service.

To basic salary we have fundamental objections. (Applause) We are determined that we will not become directly paid salaried servants of the State, and that the control of a practitioner shall not come between ourselves and our patients. So long as the patient pays us, whether directly by fees or indirectly by coming on to our lists as in the N.H.I. arrangement, there is nobody who intervenes with a monetary consideration. We are not prepared to be in a salaried position in which the interference of a State department may come between us and the interests of our patients. Those interests must be paramount. With a salary even as small as £300 a year we shall begin

experience control, and there is nothing in the Act to prevent the Minister by regulation changing it into a full-time salary. Much of the Act will be worked by regulations which the Minister can issue at any time, and the only way of getting such a regulation annulled is by a prayer in the House of Commons, which is a very difficult and extremely unsatisfactory procedure.

Compensation and Goodwill

Two or three years ago, without prejudice, we discussed with the Government, when they said they proposed to do away with the sale of goodwill, the value of practices at that time, and, taking 17,900 general practitioners—principals—the figure of £66 millions was arrived at on the basis of 1938 values at two years' purchase and plus 16% betterment. The figure for betterment is ridiculous to-day, and therefore it is unlikely that £66 millions will go very far. I know doctors who are staying in their practices until the appointed day in order that they may then give up practice and take their compensation. Although you may get your compensation some day you will have to wait a long time for it, for the value of each practice in the country will have to be determined separately and added together before the individual share of the £66 millions can be ascertained. As I see it, that cannot be done in less than two or three years, and even if there is no difficulty over partnerships there will still be a long delay before anybody who retires will actually receive his compensation. Interest on the capital sum will be payable annually according to the Act, but our lawyers say it will be impossible to determine in the case of partnerships what proportion of interest should be paid to each partner until all the terms of the partnership have been completed. Those are quite technical difficulties, but they were made a good deal of in the discussions, though in view of the larger issues we do not want to spend too much time upon them.

We have said that we will not be paid by salary because it will interfere with our relationship with our patients, and for the sake of our patients as well as ourselves we want to retain the goodwill in our practices. I know that some people are apologetic about all this even among ourselves. We know, of course, the absurdity of the contention of Socialist spokesmen that it is a question of "selling" blocks of people. It is a question, not of selling people, but of selling or keeping the goodwill which by good work we have created in our practice, just as goodwill is created and recognized in any other profession. There is no reason why we should be ashamed of our possession of goodwill or want to give it up. Its retention is as much in the public interest as in the doctors'. It represents the capital value of doctors' good work, and the doctor should be able to dispose of it when he wants to go out of practice.

If we retain our goodwill we can retain our present method of distribution of doctors. Present methods have provided a very fair distribution, as is shown by the fact that only once in thirty-four years under N.H.I. has the Minister found it necessary to supplement payments to a doctor in order to persuade him to practise in an undesirable area. If that is so when the conditions of N.H.I. apply only to half the population, the forces of supply and demand with the whole population in the Service may be expected to suffice to fill in any gaps, and the problem should settle itself. If it does not, the Minister still could have power, such as he has to-day under N.H.I., to offer special terms to somebody for a special place.

If we surrender our right to dispose of our goodwill we have the position set out in the Act whereby the Minister retains the power to say that a man shall not practise in a particular area. Remember that with regard to the injunction against practising in a particular area it is not only the people who come in after the appointed day who are affected, but any doctor who wants to change to another district. To such a doctor the Medical Practices Committee could say that there was no room in the area to which he wanted to go. That is the effect of what is called negative direction in the Act. The amount of movement that takes place in the profession is astonishing and at first hardly to be believed. During the war the Association set up at Headquarters a register of all medical practitioners with their jobs and localities, and in order to keep track of the changes of address and the movements of doctors the Association keeps six whole-time clerks fully occupied. Imagine

the problem which would face a Medical Practices Committee set up with the object of deciding whether a doctor making an application should be allowed to go to a particular area. The Minister says it would become automatic. We say, well, if it is automatic it is unnecessary, and whichever way you have it we don't want it.

Permissions and Controls

Having dealt with some of the more personal problems, Dr. Dain touched briefly on the remaining matters. One of these was the point that although all in practice on the appointed day might go into the Service, after that day it was necessary to get permission to go in. In 1911 Mr. Lloyd George made no difficulty on this point, but the present Minister would not concede it. He had said that he must have the right to refuse if he wished, and he remained tight on that, and said that doctors were free to stay out. Of course they were, but if the Service was the only means of earning one's living there was not much freedom about that.

Again, he had specifically refused any right of appeal to the courts, arguing that if he was to be answerable to Parliament for the success of the Service he must not be put in a position where he had to answer for a doctor whom he was forced to retain. The profession held that there should be a right of appeal from any decision of a tribunal to remove a name from the lists or from an adverse decision of the Minister.

A word or two on the hospital position. How were the staffs going to be affected? Somebody had said that the consultant on the staff of a hospital would have a position of great security and would be very much better off. But he had attended a meeting the other night of the Marylebone Division at which one Harley Street man in a telling speech said that all this talk about security in the Service for consultants was just rubbish, and that his only security was in his own good work. The Minister would have the power to alter the consultant's remuneration and terms of service. He would be in a salaried service.

In general practice they were enabled to adjust fees to changing money values, but when their income or the bulk of it came from a Government department they would have no such freedom. Those who were in insurance practice had known how in a slump the capitation fee was immediately reduced and with what difficulty it was raised again to meet different conditions.

Finally, there was the question of the membership of health committees of local authorities. Under the Education Act there was co-option to education committees of people interested in education, including teachers, but when it was suggested that local authorities should be compelled to co-opt doctors to their health committees the Minister said that he could insist on nothing of the sort and that it was improper to ask for it. But it had been done in the parallel case of teachers, and he hoped that when it came to the amendment of the Act this point would be insisted upon.

The Plebiscite

Dr. Dain continued: On January 8 there will be a meeting of representatives to consider details of the plebiscite and the lead to be given to the profession. On January 31 the forms of plebiscite will be issued, returnable by February 14. We are having prepared a concise statement of the points in the Act to which we are opposed and the reason for which we oppose them. This will be sent to every practitioner on the Register.

The plebiscite is not the end but the beginning. We may get an enormous majority against service. The Minister is banking on the supposition that that majority will not be real and that it will dissolve away by July 5, by which time he thinks he will have enough people to enable him to start the Service. That is what I have in mind when I say that action begins when the plebiscite result is out.

I have in front of me the draft form which will be put next Thursday to the Representative Body. I was in favour of the putting of only one question: "Are you willing (unwilling) to enter the Service?" But there are people under contracts of various kinds—whole-time officers of the Ministry and of local authorities and other bodies, medical teachers, and so forth.

We had to reconsider the form of question in the light of that fact and of the distribution of doctors in various types of occupation.

Dr. Dain here read the instructions on the draft plebiscite form and the proposed questions. He explained that the estimate of 13,000 general practitioners as constituting the strength of the vote required to give the necessary majority to justify the Association asking the profession not to accept service was the result of very careful thought. It was estimated what minimum of general practitioners the Minister would require in order to start the Service. It was decided that without more than 8,000 he could not possibly do so. The total number of general practitioners who could be available, after allowing for certain alien practitioners who might by that time be permanently registered, was computed at 21,000. If there were at least 13,000 who said they would not take part it was quite certain that a service could not be started.

We have tried to frame the questions (Dr. Dain went on) in such a way as to avoid any possible ambiguity. I see no reason why we should not have practically 100% of disapprovals. (Applause.) Even the public health medical officers and other people in whole-time employment see the red light in this Act. I have been asked that the plebiscite form should contain a legally binding agreement not to enter the Service. But it is not possible to construct such an agreement applicable to everybody, nor to have it signed and at the same time say that the vote would not be disclosed. In addition we do not want people to give legally binding agreements in this plebiscite. If we have a satisfactory majority in the plebiscite I suggest that each area in its different groups, perhaps through its Panel Committee, should get down to the practising doctor, and that doctors in their own areas should agree with one another on a form which they can sign not with the B.M.A. but between themselves. (Applause.)

If the B.M.A. organization is as good as I think and hope it is we should be able to do that between now and July, and make certain that the Minister will have no ground whatever for supposing that he will have enough doctors to start his Service.

Reassurances

What are the things which make it difficult? Here we come to the horrible word "fear." What are we afraid of? The consultant says, "On July 4 my present appointment to my hospital ceases. The hospital belongs to the Government and I must enter into a new contract. If I do not I shall lose my hospital appointment and with it my consulting practice." Fortunately that fear has little foundation. The Government will not be in a position to offer a contract to any consultant by July 5. The Spens Specialist Committee has still to report. After it has done so, arguments have to take place with the Treasury and with consultants themselves as to how it is to be implemented, and it will certainly be the end of the year before any terms can be offered to consultants. Their fears about replying "No" can be dismissed, and there is no reason why consultants and specialists should not stand in with the whole profession. (Loud applause.)

What about the general practitioner? One of them may say, "I am very much opposed to this Act, but I cannot afford to stay out. I have got boys at public schools, expenses are heavy, I must not take the risk." If one points out to him that being a man in well-established practice, as presumably he is, he stands to lose financially rather than to gain by accepting the new service, he may say, "But what if the panel cheques do not come in so that I may meet pressing liabilities?" Well, the Act provides that National Health Insurance stops when the other Service begins, and if you prevent the other from starting then N.H.I. will not stop and so you need not be afraid.

The general practitioner is in this cleft stick, that if the Act starts and he has not come in, then he loses his right to compensation. But if the profession decides to stay out, then we retain our goodwill, Mr. Bevan can keep his £66 millions, and we shall lose nothing. If there be difficulty of any sort that we have not foreseen then in one form or another we have a reasonable sum of money by which men might be helped over a short period to maintain their income and pay their insurance premiums, but there will, of course, be a great many doctors who will not be affected in that way. We shall

go on attending our patients, private and other. Here I am rather inclined to quote a leader from the *Daily Express*, which asks where the public come in. The Service is going to cost £152 millions. But there will be no more doctors than before, no more nurses, no more hospital beds, nothing that anybody will get that he cannot get to-day, although the country will be spending £152 millions to get it.

Dr. Dain concluded: The profession wants a lead. I as Chairman of Council must be the spear-head of the Association in this matter. I say that the new Service as propounded in its present form is entirely unsuitable, entirely improper for us to accept, and we should endeavour to persuade our colleagues to vote against accepting any service under the Act in its present form. The B.M.A., so far as I have any influence, and the Representative Meeting will most certainly stand firm for that position. This is a demand for action—and the action is up to you. (Loud and prolonged cheers.)

QUESTIONS

At the conclusion of the address written questions were handed up to the platform from all parts of the hall, and were answered by Dr. Dain for half an hour or more until the Chairman asked the meeting to have some regard for the speaker's physical resources.

The first question was about partnerships. Dr. Dain said that they had been quite unable to obtain from the Minister's officers or the Minister himself a satisfactory statement on the position of two partners who were receiving by their agreement unequal shares. The wording of the Act seemed to make it impossible to arrive equitably and safely at any distribution of profits between partners except by each just taking what he actually earned himself. They had told the Minister that they considered that the Act would be certain to destroy partnership and to deal a serious blow to group practice in any form.

Asked what was being done to enlighten the general public on the position, Dr. Dain said that as soon as it was known what the answer of the profession was in the plebiscite the public would be approached and fully informed of the position. The most important thing to put to the public was the risk they ran of losing the undivided loyalty of the doctor as a result of the introduction of basic salary.

Another question was, "What percentage of doctors pledged themselves against the Act in 1913 and what proportion of that percentage adhered to their pledge?" Dr. Dain replied, "Somebody thinks we do not know what happened in 1911-12. We were then dealing with a more approachable Minister, who had given way to the profession on the principles they stood for, but did not give them enough money to start with, and as he raised the price from 4s. upwards, when he got to 7s. 3d. a large number thought that was enough and came over. The position does not arise to-day. Besides, we have better organization now, and we will jolly well see it does not happen this time." (Applause.)

Asked what steps would be taken to inform the public of the true implications, Dr. Dain said that they might take from him that very effective steps would be taken. In general the Association was now on excellent terms with the Press. The Association had a very efficient public relations staff.

In reply to another question he said that in fixing on the figure of 13,000 general-practitioner votes against entering the Service allowance had been made for men coming out of the Services and newly qualified men finishing their hospital jobs.

What was the position of the whole-time medical officer a local authority automatically transferred to a Hospital Board on the appointed day? Dr. Dain said that such a man was already in a salaried appointment and would continue to do his work. There was no reason to think that a large number of these men would not express themselves as against the Act.

Would not Mr. Bevan try to implement his scheme whether the doctors were there or not? Well, Mr. Bevan was very determined. He had declared to the dentists that he would start a service on July 5, dentists or no dentists. Were such expressions anything more than hot air?

In reply to one question Dr. Dain explained the position under the Act with regard to midwifery. The Minister had taken power to determine the qualifications of the doctors who

should undertake midwifery under the Act, and the profession had said that that must come out.

In the conversations Mr. Bevan had made it clear that no practitioner would be allowed to charge fees to persons on his list. Such persons could go to another practitioner, who would charge them a fee, but Mr. Bevan seemed to think that this should never be more than a single consultation fee, and that if a patient was dissatisfied with his doctor he should change to another list rather than seek treatment outside the Service. The profession did not assent to that.

When would Mr. Bevan want their answer? He had said that they would have six months to make up their minds. There would remain some months after the result of the plebiscite was known, and if the individual intended to accept service, or if the profession indicated its willingness to accept, this could be done any time up to July 5.

Some questions were asked and answered about the imminent accession of a number of alien doctors, displaced persons, on the permanent Register. Allowance had been made for these in the various computations. Incidentally Dr. Dain mentioned that as a member of the Council of the Royal College of Surgeons he was aware that a large number of young men evidently thought they would be better off in the new Service as specialists than as general practitioners and were seeking special diplomas, not always with success.

Might it not nullify the result of the plebiscite if the Minister afterwards made some alterations in the conditions? Well, the

Minister had shown no sign of weakness, and if the profession gave an emphatic "No" he would find it difficult to start offering one thing or another between now and July 5.

Why not adopt the policy of passive resistance? The answer was that passive resistance was difficult, and what was wanted was not passive but active resistance as soon as it was known that the vote in the plebiscite had gone in a certain way.

Concerning hours of work, these must depend on the kind of work doctors individually undertook. "We shall never, I hope, expect that doctors under any conditions of employment will do office hours. We must be at the disposal of our patients when they are ill."

What was to prevent the Government enforcing on the State doctor union rules—an eight-hour day, a forty-hour week? "We are the people who will prevent any Government from enforcing orders upon others."

In closing the questions Dr. Dain said that members of the profession in other countries were watching events here. He had been impressed by this when attending the World Medical Association at Paris in September. Representatives of medicine in other countries were most anxious to know whether British doctors could stand for their own freedom.

A hearty vote of thanks to Dr. Dain was proposed by Dr. E. L. K. Sargent (Wimbledon) and seconded by Dr. S. A. Forbes (Croydon) and enthusiastically carried. The proceedings closed with a vote of thanks to the Chairman, moved by Dr. N. E. Waterfield.

THE PROFESSION AND THE MINISTER

DR. HILL'S ADDRESS

What the chairman described as a historic meeting was held in the Great Hall of B.M.A. House, London, on the evening of New Year's Day. It was convened by the Metropolitan Counties Branch and was addressed by Dr. Charles Hill, Secretary of the Association. The gathering was probably the largest ever assembled in the hall, where large numbers had to stand or sit on the floor throughout the proceedings, and, even so, many could not gain entrance and the speech was relayed to other parts of the building.

Dr. Hill spoke for an hour and 25 minutes and answered questions for a further half-hour. He made a careful and dispassionate survey of the Minister's reply to the case which had been put forward by the Negotiating Committee for amendment of the Act. A reminder of the fights of former years was on the platform in the person of Dr. Alfred Cox, for more than twenty years Medical Secretary. The gathering included a relatively large proportion of consultants.

Dr. R. W. Cockshut, chairman of the Metropolitan Counties Branch Council, who presided, said that it was now a considerable time since the Representative Body committed the honour and future of the medical profession into the hands of the Negotiating Committee. During those long months the Committee had met the Minister and his officers, and now the trust was handed back untarnished. Nothing had been given away.

The present great meeting, Dr. Cockshut continued, was the first large meeting of doctors to be addressed by Dr. Hill since the Minister's reply. They had reached a stage when the future of medicine was at stake; but the future of medicine was not in the hands of the Government or of Mr. Bevan, it was in the hands of the doctors themselves, and they had it in their power to ensure that the traditions they inherited and the hopes they held for the future were secured.

The Minister's Reply Examined

Dr. Charles Hill, who was warmly received, said: It is my job to-night to survey the reply that the Minister has given to the Negotiating Committee. That reply is prefaced by a series of observations addressed to individual members of the profession. Those observations are couched in seductive terms, possibly with a faint air of prefabrication about them. But we must not allow personalities to confuse the issue, and equally we must not allow the sweetness of the terms which the Minister uses to obscure our understanding of the real character of his reply. We must be careful not to mistake the gloss, the varnish, the veneer for the substance which lies beneath.

We are told in the Minister's reply that any doctor will be free to enter or not to enter the Service, or partly so and partly not; there is no compulsion. In one sense true, but if this Service comes into being in its present form the vast majority of general practitioners will not find the position to be that of entering or not entering. If the State is paymaster in respect of the bulk of the population many practitioners will find themselves faced with the choice of coming inside or starving outside.

The Minister goes on to say that the word "service" is perhaps a misnomer; but it is the word he himself has used in the designation of the Act. He says we shall not be Civil Servants. True, in the accepted sense of the term, but general practitioners and consultants will be salaried officers of an agency of the State, and, what is more, they will be entering a service which is administered by Civil Servants.

He then tells us how the doctor will be paid, and with a delicacy all his own he begins that summary by quoting the maximum remuneration. With the maximum number of persons on the practitioner's list he gives that remuneration as £3,300 a year. It would have been fairer to have recalled that under National Health Insurance to-day, with a maximum list of 2,500, the average is 1,000 insured persons on the list, and it may be calculated from this that in the future, in a service available to and utilized by 95% of the population, the average list will be approximately 2,000, and the average annual remuneration gross from the Service will be £1,816.

The Minister says there is no rigidity about the figure 4,000. We may infer that there is no rigidity either way, that the number can be increased or reduced by regulation as time goes on. He also says in an attractive phrase that if the doctor who has entered the Service wants later on to stop practice for any reason he can draw his compensation at once. There may be some who have turned over the prospect of entrance into the Service and speedy resignation, collection of compensation, and thereafter concentration upon private practice. I have been at pains to inquire exactly what those words mean. They mean that if a general practitioner emigrates to another country, if he removes himself from general practice altogether and takes up another form of medical practice, or if, leaving his own area, he goes into another to engage in private practice, he will then be able to draw his compensation and continue in private practice in the area in which he resides. I mention this to show that the remarks with which the Minister prefaces his reply should be scrutinized with unusual care.

Direction and Distribution

Passing from this preamble to the more detailed reply of the Minister we notice his statement that he has examined the seven general principles of the profession and does not believe that anything in the new Service is really in conflict with them. I would remind you of our principle which states that anything tending to make the medical profession whole-time salaried officers of central or local government is contrary to the best interests of the public and of the profession itself. The main question which we have soon to answer is whether in fact the proposals do involve such a tendency and, if so, what we are going to do to arrest it.

The Minister goes on to deal with distribution. Existing general practitioners will be permitted to continue in their own areas, but any newcomer into an area will be required to obtain permission. We have said that general practitioners should be free, without the necessity of permission from anyone, to set up in public practice in the area of their choice. We have objected to a state of affairs in which governmental licence is necessary before such choice can be exercised, and we have gone on to argue that by the creation of a comprehensive service and the payment of a capitation fee such errors of distribution as exist to-day will rectify themselves in course of time. We admit that where under-doctoring can be substantially proved it will be the Minister's duty to correct it by appointing to that area a general practitioner who is willing to go there.

But study the Minister's reply on direction or distribution with particular care, because the Minister rests his case for the abolition of ownership of goodwill in general practice upon the necessity for controlling distribution, with resultant interference with sale of goodwill. The Minister's first argument in favour of his distribution proposals is that no doctor in the public service can be allowed to attract to himself public money without public or official permission. Implicit in that argument is the assumption that the doctor would increase the public expenditure by choosing an area where he was not needed. That is not the case. The medical pool of capitation fees will be related to the number of persons who use the Service, and would not involve an increase in public expenditure for doctors to choose the area in which they desired to establish themselves in public practice. At least that would be the case but for the basic salary proposal. Indeed, it is in the distribution paragraph that we begin to see the motive which lies behind basic salary.

The distribution of doctors, says the Minister, would be in the hands of a predominantly medical committee, not subject to his direction—a plausible argument until we study the document lower down, where he tells us that the Medical Practices Committee is only going to find a few areas which are under-doctored. He is doing their work in advance for them, while at the same time he claims that they are an independent professional body.

He states that the Minister intervenes only where a doctor, desiring to go to a particular area, is refused permission by the committee and appeals to the Minister. The most he can do, he says, is to reverse a decision in the doctor's favour. That is a piece of special pleading. The main work of the committee will be to select from among the competing applicants, and when a doctor appeals against a decision he will be in fact appealing against a decision in favour of another doctor.

He tells us that there will be few areas where there is no need for new public practice or replacement. If that be true he is proposing to establish a vast system for the licensing of general practitioners for the solution of what he himself submits will be the problem of a few areas. The whole of his case for the abolition of goodwill is built on the argument for better distribution, and yet he says that the problem, like the servant girl's baby, is only a small one and that this control will be exercised only in a limited field.

Cumbersome Machinery

We stated in our document that the whole machinery was cumbersome. The Minister denies it, but I challenge anyone to deny that the Act lays upon the Medical Practices Committee the obligation in every case in which a doctor seeks to

establish himself in public practice anywhere to satisfy itself that the doctor is needed in the area.

He says that the Medical Practices Committee, advised by the Local Executive Councils, will keep itself informed of the state of affairs in general practice throughout the country. This great meeting is a meeting of a proportion of the practitioners of London, and that one committee of wisacres has to be fully informed of the detailed conditions of the areas in which you practise so that should one of you, unfortunately, die it will be immediately possible for the committee to determine whether the circumstances demand your replacement or not.

The experience of the Central and Local Medical War Committees proved that the problem is an immense and laborious one. There will be placed on the committee a burden which it cannot sustain. You may think all this relatively unimportant, but it builds up the picture with which we shall finish, of the unwillingness of the Minister to make any change in this Act in principle or detail whatever the strength and validity of the arguments we advance.

The Ownership of Goodwill

Let me pass on—for I cannot pretend to be comprehensive—to the ownership of goodwill. The Minister declines to shift from his position. During the discussions there emerged the problem of partnership agreements. It is a technical problem, but the examination of it is an indication of the Minister's mind. As ownership of goodwill is abolished, with compensation, the authors of the Act thought it right and proper to define circumstances in which certain transactions would in fact constitute sale and purchase of goodwill. There is a penalty for such transactions—fine and/or imprisonment. For example it is defined as an offence when two partners working together divide the emoluments in proportions other than those in which the moneys were earned. To that section there is a proviso exempting, according to the Minister, all existing partnership agreements, which agreements remain in operation as if no service had been introduced.

We took legal advice on that, the best we could obtain from leaders of the Chancery Bar. Those of you who are interested in the legal argument will find intellectual entertainment in counsel's opinion (*Supplement*, Dec. 20, 1947 p. 151). They state that the Minister is wrong in his interpretation, and that only a proportion of partnership agreements, not the whole, are exempt from the disciplinary provisions, and they go on to say:

"If Sections 35 and 36 are allowed to become operative without amending the profession and the Ministry alike will labour under embarrassing uncertainty on matters of great importance until the debatable matters have been finally adjudicated upon, and in the meantime steps may have been taken on the footing of a construction which is ultimately found erroneous with unfortunate consequences to all concerned. In our opinion it would involve a real hardship to the practitioners concerned if they were required to submit to such uncertainty when it has been clearly foreseen and can be removed by an amending Act."

That is the opinion given, that the Minister's interpretation is wrong and that in any case such ambiguity exists that it is a matter of embarrassment and danger to members of partnerships to require them to decide whether or not to enter the Service without knowing whether the partnership deeds into which they have entered in different circumstances are still valid after the appointed day.

Counsel go a stage further. Taking the Minister's own interpretation of the Act, they go on to show that the Minister is incapable under the Act of putting his own interpretation into operation, that the Minister is incapable in law of paying the interest upon compensation moneys which the Act he promised shall be paid to individual practitioners. The Minister's reply in effect is this: "If in future I am proved in the courts to be wrong then I shall introduce legislation to put myself right." (Laughter.)

You see the position. It will be fought out in the courts by practitioners at their own expense, perhaps taken to the House of Lords at their own expense, and when that has been done the Minister or his successor, if he decides to observe the promise of the present Minister, will introduce legislation to put it right. But nothing can put right transactions which have

taken place after the appointed day and before such a decision by the House of Lords—transactions which have been undertaken in the mistaken view that the Minister's interpretation was correct.

The significance of this is in the Minister's real intention. Let me tell you what it means if the Minister's interpretation is right. It means that where two partners join the Service and one is required by the partnership agreement in certain circumstances to purchase the share of the other he may still do so, but he may be in the position of putting down £2,000 and registering for compensation £1,500 or less. True, the reverse may obtain. It is theoretically possible for the agreement to provide for a less generous payment than the payment from the compensation fund. But where one partner enters the Service and the other does not—and, mark you, the profession is free to join or not to join—and the one not in the Service dies or retires, the man in the Service may by the agreement be required to buy the practice of the man who had been outside, and having bought it there is nothing in the fund to compensate him for the loss of his capital value, despite the fact that, being a member of the Service, he is precluded from selling what he has bought.

If, on the other hand, circumstances should operate the other way, and the man inside the Service should die or retire, the man outside the Service is required to purchase the practice of the other. He can touch the income from what he buys only by himself entering the Service, and if he enters the Service he loses his power to sell his own practice and the share he has bought, without a penny of compensation. What does the Minister say? He says it is unfortunate that there is no compensation provided in the Act for the practitioner who, being in the Service, is required to buy the share of his partner who was outside the Service, but he has hit upon a way of making some money available to him. Money, after all, is saved in the compensation fund. If a man inside the Service sells the practice to a man outside the Service the Minister will use the money saved to compensate the man inside the Service who has bought the practice outside.

You know what that means. It means that for the man outside the Service who is required to buy a share of a practice inside the Service there will be expropriation, robbery, call it what you like. He is mulcted of a sum of money, he is prevented by law from obtaining it, and the Minister in effect says, "To the extent I have mulcted the man outside the Service I will use the money I have pinched to compensate the man inside the Service." Contributions to the church offertory are evidently welcome, even from the proceeds of picking pockets!

If the Minister is right, the situation I have described is the direct result of his interpretation. If he is wrong—and he waits for us to prove him wrong—he is going to introduce legislation to put himself right. The Minister has proved impervious to argument, legal or other. He is inviting members of partnerships to join the Service without his taking the trouble completely to clarify the position which will obtain if they do join the Service.

It is difficult to be dogmatic in one's estimate of the future but we have felt that this new Service in a number of ways renders it less likely that there will be partnership practice and assistantships with a view. You will realize the peril—safeguarded to some extent by the Medical Practices Committee—in which partners will be placed. For example, if an assistant is paid substantially less than he is held to be worth and is subsequently admitted to partnership it may be held that there has been a concealed sale and purchase of goodwill.

The Doctor's House

I must refer to the doctor's house. Should a doctor die and his widow sell the house to the incoming practitioner it will be an offence if the consideration for the sale is substantially in excess of the consideration which might reasonably have been expected if the premises had not previously been used for the purpose of medical practice. The widow, if successfully prosecuted, is liable to fine or imprisonment. The Minister's reply on this point is significant. He says that there is no risk of committing an offence if the house is put up to auction. The Act does not say anything about auction or method of sale. When the Minister does not like our interpretation of what the Act

says he declares that it must be left to the courts to decide, but when the straightforward reading of the Act is inconvenient to him he gives his interpretation and asks us to accept it despite the plain reading of the words.

The Remuneration Proposals

Now for remuneration. You know the general conception. Take 95% of the population of the country, multiply it by 18s., and that is the medical pool. Out of the pool come mileage, temporary resident payments, payments for anaesthetics, emergencies, and so on. Take mileage out, and the pool becomes comparable with the central pool under N.H.I. to-day. That pool will be divided among local executive councils in a proportion, taking as index figure the number of persons in the area who have signed on to doctors' lists, plus one-third of those who have not.

In his illustration the Minister puts the maximum remuneration first. I do want to point out that in a free service which covers the whole population the number of items of service per person will rise. Since the inception of N.H.I. the number of items of service has trebled for the same section of the community. The number is between 5 and 6. If we take 5, then for 4,000 public patients there will be 20,000 items of service a year, considerably more than 100 items a day in the winter months and 60 to 70 in the summer. I mention that in order that it may be appreciated that the maximum on the lists is not to be everybody's prerogative—indeed, it is not within everybody's physical capacity. By analogy with N.H.I. the average is likely to be 2,000.

The Minister says that over and above the payment for the 4,000 public patients there will be lots of other things—public and private fees, maternity payments, mileage payments. What he does not say is that all district medical officer appointments will go, incidentally without a penny of compensation for loss of office; the work of police surgeons and post-office medical officers will contract at first and afterwards go; and that to undertake midwifery in the public service will be inconsistent with a complete list, indeed will inevitably mean a list which is substantially less than the maximum. In many areas private practice will be virtually non-existent.

But take the average—2,000 patients, giving a gross income of £1,816. An issue which arises at once is: Does this conform to Spens? The Spens Committee examined the range of general practitioner remuneration, and the report has been accepted by both sides. The Spens Committee, speaking in terms of pre-war money and net remuneration after allowing for practice expenses, said that 75% of practitioners should obtain over £1,000, 50% over £1,300, 25% over £1,600, and 10% over £2,000. Taking the 50% figure of over £1,300, and adding 30%—a low computation—as the betterment factor to bring pre-war values up to post-war, we get £1,690. Adjust this for practice expenses of 33½%—again a rather low figure on the returns prepared for the Spens Committee—and we get for 50% of practitioners a gross income of £2,535 or over. Can this be compared with £1,816 as the Minister's figure for the gross income of the practitioner having the average number of persons on his list? That "average" man is not quite the same as the "middle man" in the Spens figures, but the difference is probably not great; the difference between £1,816 and £2,535, however, is considerable. Even allowing for the value of the Government's contribution to superannuation the Minister's proposals do not appear quite to tally with Spens in the middle ranges. In the upper ranges the gross post-war figures for the Spens 10% group would be £3,900, comparing with £3,332, the Minister's figure for the man who has 4,000 public patients.

The Basic Salary

There is nothing more to be said about remuneration except this: there will be a basic salary of £300 a year, providing there is sufficient speed in the increase of the list. The basic salary is paid on the understanding that you need not have it for long. The effect of it is this, that the capitation fee for the first 1,000 patients is 21s. 2d., and for every patient over 1,000, 15s. 2d. I am taking the assumptions that 95% of the population are on doctors' lists and that 17,900 practitioners join the Service. The curious thing is that the greater the number of practitioners who join the Service the smaller will be the

capitation fee, for a greater number of sums of £300 will have to be taken from the central pool before the rest is distributed. The tapering capitation fee of which we have heard so much comes back in a new form.

Appeal to the Courts

You know the Minister's answer about the right of appeal to the courts. It is "No." He asks how could he be answerable to Parliament for the conduct of a doctor whom the courts had restored? You see the implication. He finds himself unable to accept the position that his verdict or the verdict of the tribunal should be subject to challenge in the courts. We have argued that in a service of these dimensions it must not be possible for a practitioner to find himself unable to earn a living while he is still regarded by the General Medical Council—another arm of the Government—as a fit and proper member of the medical services of the country.

The Hospital Aspect

Having completed this rapid survey of the general practitioner position, Dr. Hill turned to the hospital aspect:

There is one point in our original position which has not been pressed—the ownership of hospitals by the State. It was inevitable from Beveridge onwards that the State should accept financial responsibility for the provision of hospital beds and medical care therein, and the Government took the decision that led inevitably to ownership of hospitals, local authority and voluntary, by the State.

Expressing a personal view, I regret that we have not taken a stronger line in relation to that issue. For too long we have been making the bland assumption that to transfer something to the State is inevitably to ensure that it will be properly, wisely, and soundly administered. But there was no uprising of public or professional opinion on that issue, and the very fact of the passage of the Act so damaged the finance of many voluntary hospitals as to make the change almost inevitable. Therefore our representations were on other issues, the most important being that the Act enables a hospital monopoly to be established, transferring automatically to the State all the non-profit hospitals and giving the Minister also power to acquire land on which he may cast a lustful eye and which may include any hospital buildings. The Minister has also power to take over nursing-homes, so making independent practice difficult if not impossible. The hospital beds will be of three kinds, public, private, and intermediate, in which last the patient makes a payment only in respect of the amenity of the accommodation. There would be grave peril to consultant private practice if it were decided to develop intermediate accommodation at the expense of private.

When we met the Minister—I think I had better draw a veil over his demeanour in the discussion on the general practitioner phase—a strange blandness and friendly accommodation came over him as he turned to the hospital and consultant aspects of his reply. I wonder if he hopes to divide the general practitioners and the consultants in the dispute that lies ahead. Mind you, there was more sweetness of manner than promise to amend. He did not promise to amend anything. He said, "Of course, I shall not take over nursing-homes, subject to what the Regional Board has to say." He said, "I recognize the case for removing the ceiling on fees on a proportion of private beds." He gave other assurances.

I am not casting doubt on the word of the Minister as a man. But I do want to remind you of the danger of regarding ministerial assurances as binding on other Ministers. In November, 1939, a letter from the three Presidents was published in the medical press, saying that there was suspicion amongst some doctors that the Ministry of Health might be proposing to use the E.M.S. as the thin end of the wedge for a post-war State medical service, and assuring the profession, on the highest authority, that nothing was further from the Minister's intention and that all such fears were groundless. "That the voluntary system will continue there is no reason to doubt." That was based on the word of one Minister, an assurance upon which the profession co-operated in the E.M.S. during the war, and it has been—quite naturally—completely ignored by another. Every hospital except those he does not want will be the property of the Minister; the Minister will determine by regula-

tion the remuneration of general practitioners and consultants, and can change them when he likes; the Minister can increase the basic salary element in general practitioners' remuneration, and do it by regulation; the Minister can convert the consultants into a whole-time salaried service by regulation; he can make private practice for consultants well-nigh impossible, so compelling them to seek whole-time salaried service, and he has the power to establish a hospital monopoly and to make impossible the development of private hospital services, or voluntary endeavours of one kind and another.

The Decision Ahead

After a brief examination of the superannuation proposals Dr. Hill drew to his conclusion. He had with some necessary labour gone over the main features of the Minister's reply, and he went on to ask:

What does it all add up to? There is one criterion by which as a profession we can measure these matters. It is not, I hope, a financial criterion. It is whether these proposals do or do not bring us closer to a whole-time salaried service of the State. That is the crucial issue, and on that issue we can command the support of the overwhelming majority of our profession.

These proposals taken together add up, if not to a whole-time salaried service, to a form of service which could easily be translated into such State service. The general practitioner will no longer own his goodwill, be unable to enter public practice without the permission of a Whitehall Committee, be compelled to take a proportion of his remuneration in the form of salary, it being left to the Minister to determine in future—by the process of regulation—what that proportion shall be; in the hospital field, there is a possibility of a hospital monopoly; with the future of independent practice in the hand of the Minister, the future of the consultant section of the profession is in the hands of the Minister. Does that add up to a salaried service under the State? Does it lead inevitably to a whole-time salaried service of our profession? What is the evidence?

We have the evidence of the previously announced policy of the party in power as stated from time to time, never more picturesquely than when the Minister said, "You do not pick fruit when it is green, you wait until it is ripe." We have the evidence that these proposals commend themselves to those who honestly believe in a whole-time salaried service. Some of you may have read of the leakage in the *Tribune*. How that leakage arose we do not know. But here is a paragraph which is significant:

"Politically the Minister's firmness has been most important. If he had been weak in face of this reactionary profession, which is being remarkably generously treated both with regard to compensation and income, it would have increased doubts as to the intention to carry out a Socialist programme."

This is part of the Socialist programme. This is a first step to that end. What are we doing? The Minister has told us of our right as individuals and our right collectively to determine our attitude to this Service. We are within our rights in saying "No." (Prolonged applause.)

The Plebiscite

There will be a plebiscite of the profession. The profession will have a clear opportunity of stating both its wishes and its intentions, and if a sufficient proportion of general practitioners give the necessary indication we shall tell the Minister—in the terms of the returns of the plebiscite—to think again. If we do not get a sufficient majority—a majority which itself will offer the necessary reassurance to those opposed to this Service—we shall have to advise you that resistance is impossible and we must make the best of the situation. There must be a sufficient majority of the individual members of the profession, and it will be known in advance what that majority must be. Therefore practitioners opposed to the Service will know that they will be called upon to decline to enter the Service only if a sufficient majority of the profession is similarly determined and will act with them.

There will be no question, if that majority is achieved, of asking doctors to discontinue their work. Consultants will be asked to go on with their hospital work, but not to sign at

contract with Regional Boards, no more and no less. They may be reassured that such is the time which the Specialist Spens Committee may take to report and for that report to be examined that it is extremely unlikely that any Government will be in a position to offer them any contract until well after the appointed day. Other members of the profession will also be asked to go on with their work. General practitioners will be asked to go on with their work for their patients, but on a non-contract basis.

If we get a sufficient majority the period of uncertainty will not be prolonged. The first stage is to express yourselves quite plainly in the plebiscite return. It has been said sometimes of the B.M.A. that it has not given a lead. Let there be no mistake on this occasion. The lead is plain. In the view of the Council of the Association this thing is wrong, and its advice is that our profession should stand firm in resisting it. (Loud applause.) There is no ambiguity of any kind there.

A Word to the Consultants

To our consultant colleagues, I would say it may be true that the battle ground is in the field of general practice. To some extent that is inevitable. But it is also true that the freedom of one section of the profession is of paramount importance to the freedom of the whole. We say to our consultant friends, "We need a united profession, a profession in which all its elements, whether consultant or general practitioner, whether directly affected or not, acknowledge their duty in this regard to the public and to the future of the profession to which they all belong." The members of the profession in other countries, especially in the Dominions, are watching events in this country with anxious interest. It is our duty and our opportunity by standing firm to secure that this thing does not come into operation in its present form. (Renewed applause.)

Speaking Personally

In conclusion Dr. Hill took his audience back to a similar meeting in that Great Hall in the summer of 1943:

We were then considering a document which had been produced by Mr. Ernest Brown for a whole-time salaried service under the State. Such was the reaction of that meeting that very soon afterwards Mr. Brown placed those proposals, in his own words, in the discard. At that meeting I necessarily expressed a personal view, because by the sequence of events it was not possible to express an official view.

In the years between it has been my job to try to interpret the different moods of the profession (and they have differed over the years). It is four years to-day since I was appointed to the secretaryship of the Association, and throughout those four years I have been in all the discussions which have taken place. From time to time I have had my doubts on one point or another; at times it has been difficult to see the wood for the trees. All of us in the last few years seem to have had some difficulty, possibly as a result of the war, in seeing big issues in their full clarity.

We were right to undertake discussions during this past year, for we had everything to gain and nothing to lose by frank and detailed criticism and comment. The events of recent months have made it absolutely clear that these proposals mean and are intended to mean a whole-time salaried service under the State. And I have no doubt in my mind that our profession would be right to reject this thing by an overwhelming negative vote in the plebiscite shortly to be taken.

This is the last chance to do so. If we do have to enter the Service in its present form, life will still go on, but medical practice will have changed its character. There will be lost to the profession and to the public a form of practice which by its emphasis on the individual, by its insistence on the doctor-patient relationship, by its human yet efficient character, has been a credit to this country. These will be lost and lost for ever unless the profession forgets its past differences, learns a new loyalty, and stands with firmness for its principles. It is now or never for the profession to which we belong.

QUESTIONS

The remaining time of the meeting was occupied with questions sent up from the audience. Among the questions was, "If partnership is fraught with difficulties will not group practice

have difficulties still greater?" Dr. Hill said that the fair answer was that if the Act came into operation in its present form there would be an entirely new kind of partnership difficult to envisage at the moment.

"If the B.M.A. considers that the new Service will mean so much extra work for the general practitioner, why is it opposed to regular hours and rota of duties?" Dr. Hill replied that in so far as mutual arrangements between practitioners were concerned it was a matter of common sense that they should be made. A whole-time salaried service might well mean a more ordered and leisurely life, but they could not have it both ways; they could not insist on the freedom of the individual doctor to conduct his practice in his own way and at the same time expect to have the conveniences of a whole-time service.

"What guarantee is there that the vote in the plebiscite will be adhered to by the individual?" In the first stage, none. They had to rely on the integrity of the profession. At the same time organizational steps would be taken to induce in the profession that warm feeling of fellowship which came from the knowledge that individuals were not standing alone. It was necessary to get away from the mentality which assumed that the profession was incapable of loyalty. This was an issue which affected the profession as a whole, and as a united profession they would deal with it.

"What will be the position of the man with specialist qualifications who wishes to continue in general practice?" Such an individual would be able, if he chose, to remain in general practice. There might be a movement to encourage those who were doing both general practice and specialist work to decide to go one way or the other, but there was no need for such a man to fear that he would be required to leave the general practice he preferred.

"What is going to happen with regard to 'displaced persons' on the temporary Register?" There would be added to the permanent Register within the next few months, as the result of an Act which had just received the Royal Assent, a considerable number of alien practitioners who had been on the temporary Register and others who had not. There might be between 3,000 and 4,000 altogether. They would be invited to express their views in the plebiscite, but account would be taken of this body of people in calculating the size of the necessary majority. It must not be assumed that alien practitioners would not stand in with the British profession.

"What is the significance of the Minister's comment that in two years' time the position will be reviewed?" The guess was made that 95% of the community would sooner or later use the new Service. That figure was subject to review in the light of experience after two years, which was right and proper.

Questions were asked about the wording of the question in the plebiscite. Dr. Hill said that this had been the subject of most careful consideration. The wording arrived at might not please some, but he asked that, having been thought out at great length, it should be accepted. "It may not be perfect, but it will give you an opportunity to say you will not touch this thing."

In reply to another question he said that private practices could still be bought and sold if no compensation had been paid in respect of them.

Asked why £300 was chosen as basic salary, he said that he had not the faintest idea. But the insistence on a basic salary furnished the justification for the Minister's distribution proposals. The salary element was a thing that could be increased as the years went by. It was the thin end of a big wedge.

Some questioners were evidently disturbed about the position with regard to N.H.I. if there was no acceptance of service on the appointed day. It was possible, said Dr. Hill, that there might be a period of conflict during which practitioners would provide a service for their patients on a fee-paying basis. It was a risk worth facing provided sufficient strength was shown in the plebiscite returns. "If you believe in a whole-time salaried service, you will express your approval of the Act on the plebiscite form, but if you do not believe in such a service and are willing to prevent its ever happening, then you will vote the other way, and you have the assurance that action will be taken only if a sufficient number of your colleagues think likewise, that number being sufficient to compel the Minister to think again."

MEDICAL NEW YEAR HONOURS

The names of the following members of the medical profession were included in a New Year Honours List published in the *London Gazette* on Jan. 1 :

G.B.E. (Civil Division)

Sir EDWARD MILLANBY, K.C.B., M.D., F.R.S., F.R.C.P. Secretary, Medical Research Council.

K.C.S.I.

Major-General (Local Lieutenant-General) TREFFRY OWEN THOMPSON, C.B., C.B.E., M.D., late R.A.M.C. Honorary Physician to the King. Director of Medical Services, India.

K.C.I.E.

Major-General ROBERT HAY, C.I.E., M.B., Ch.B.Ed., I.M.S. Director-General, Indian Medical Service

K.B.E. (Civil Division)

JOSEPH BERNARD DAWSON, M.D., F.R.C.S., F.R.A.C.S., F.R.C.O.G. Professor of Midwifery and Gynaecology in the University of Otago.

Knighthood

Colonel DAVID CLYDE, C.I.E., M.D., I.M.S. Honorary Surgeon to the Viceroy. Surgeon-General with the Government of Bengal.

His Honour TOM EASTHAM, K.C., M.B., Ch.B. Senior Official Referee, Supreme Court of Judicature.

JOHN PARKINSON, M.D., F.R.C.P. Physician in charge of the Cardiac Department, London Hospital.

HARRY PLATT, M.D., M.S., F.R.C.S. Professor of Orthopaedic Surgery in the University of Manchester.

Professor LUIGI PREZIOSI, M.D. President of the National Assembly, Malta.

C.B. (Military Division)

Major-General (temporary) (now Colonel) STANLEY ARNOTT, C.B.E., D.S.O., M.D., late R.A.M.C.

Air Commodore PHILIP CLERMONT LIVINGSTON, C.B.E., A.F.C., F.R.C.S., R.A.F.

Surgeon Rear-Admiral JOSEPH ALOYSIUS O'FLYNN, M.D., R.N. Honorary Physician to the King.

C.B. (Civil Division)

JOHN JARDINE, O.B.E., M.D., F.R.C.S.Ed. Chairman, General Board of Control for Scotland.

C.M.G.

ERNEST MUIR, C.I.E., M.D., F.R.C.S.Ed. Honorary Medical Adviser to the British Empire Leprosy Relief Association.

C.I.E.

Lieutenant-Colonel ALFRED INNES CON, O.B.E., M.R.C.S., L.R.C.P., I.M.S. District Medical Officer, The Nilgiris, and Superintendent, Government Headquarters Hospital, Ootacamund, Madras.

Colonel PAUL HERBERT SHELLEY SMITH, O.B.E., M.B., B.Ch., I.M.S. Inspector-General of Civil Hospitals and Prisons, North-West Frontier Province.

C.B.E. (Military Division)

Brigadier (temporary) RODERIC DUNCAN CAMERON, O.B.E., M.C., M.B., Ch.B., late R.A.M.C.

Surgeon Captain CLAUDE KEATING, M.S.M., L.R.C.P.&S.I., R.N.

C.B.E. (Civil Division)

JOHN BURKE, M.D., C.M. For devoted service as a medical practitioner and surgeon in the districts of Grand Bank and Fortune, Newfoundland.

Professor NORMAN McOMISH DOTT, M.B., F.R.C.S.Ed. For services as Director in Neurology and Neuro-Surgery, Brain Injuries Unit, Bangour Hospital, Edinburgh.

Lieutenant-Colonel ALBERT EDWARD EVANS, M.B., B.S. Medical Chancery Visitor, Supreme Court of Judicature.

WALTER ALLISON GILMOUR, M.D. Pathologist, Auckland Public Hospital, New Zealand.

Lady (Dorothy) ELSLIE HUTTON, M.D. Lately Director of Welfare, Indian Red Cross and St. John War Organization.

WILLIAM GORDON MASTFIELD, M.R.C.S., L.R.C.P. Lately Medical Superintendent, Brenwood Mental Hospital, Essex.

GEORGE FRENCH STERLING, M.B., F.R.C.S. Late member and Honorary Secretary of the Radium Commission (died Dec. 22, 1947).

O.B.E. (Military Division)

Surgeon Lieutenant Commander JOHN WARD WALKER, M.B., Ch.B., R.N.

Major (temporary Lieutenant-Colonel) FREDERICK WILLIAM WHITTON, M.B., Ch.B., I.M.S. (A.M.C.)

O.B.E. (Civil Division)

HARRIET ELIZABETH ACHESON, M.D. Women's Medical Service, India. Vice-Principal and Professor of Obstetrics and Gynaecology, Lady Hardinge Medical College, New Delhi.

VICTORIA MARY CROSSE, M.D. Deputy Senior Assistant Medical Officer of Health, City of Birmingham.

THOMAS FRANK DAVEY, M.D. Medical Officer, Leprosy Service, Owerri Area, Nigeria.

Major GEORGE KENNETH GRAHAM, M.B., B.Ch., I.M.S. Lately Civil Surgeon, Peshawar, North-West Frontier Province.

Major JAMES GUTHRIE, M.B., Ch.B., I.M.S. Civil Surgeon, Tibet and Bhutan.

Major CORNELIUS JEFFCOTT HASSETT, M.B.E., M.B., B.Ch., I.M.S. Civil Surgeon, New Delhi.

NICHOLAS KEATING, L.R.C.P.&S.I. Senior Member, South Wales Panel, Silicosis Medical Board, Ministry of National Insurance.

CHRISTIAN WILLIAM FRASER MACKAY, M.B., Ch.B., Colonial Medical Service. Assistant Director of Medical Services, The Gambia.

HOFEEZUDIN SIRAJUDIN MOONSHI, L.M.S. For public services in Singapore.

Mrs. MARGARET STEWART MUNDAY, M.B., Ch.B. Lately Professor of Physiology, Lady Hardinge Medical College, New Delhi.

Lieutenant-Colonel WALTER SCOTT, M.B., B.Ch., I.M.S. Civil Surgeon, Central Provinces and Berar.

Major ARTHUR MANUS SHERIDAN, F.R.C.S.Ed., I.M.S. Civil Surgeon, Lucknow, United Provinces.

Major SAMUEL SHONE, M.D., M.R.C.P. I.M.S. Superintendent, King George Hospital, and Professor of Medicine, Andhra Medical College, Vizagapatam, Madras.

Major HAROLD STANISLAUS SMITHWICK, M.B., B.Ch., I.M.S.

WILFRED STANLEY WALLIS, M.B., Ch.B., Rotorua, New Zealand For services to returned ex-Servicemen.

OSCAR REGINALD LEWIS WILSON, M.B., B.S. Principal Medical Officer, Ministry of Pensions.

Honorary O.B.E. (Civil Division)

SAMUEL LAYINKA AYODEJI MANUWA, M.D., F.R.C.S.Ed. Specialist in the Medical Department, Nigeria.

M.B.E. (Military Division)

Major (temporary) JOHN BISHOP BORTHWICK, M.B., F.R.C.P.Ed. R.A.M.C.

Major ROY THOMSON FLETCHER, M.D., R.A.M.C.

Flight Lieutenant THOMAS HARVEY, M.B., Ch.B., R.A.F.V.R.

Major (temporary) IAN ARCHIBALD JACKSON, M.B., B.Chir. R.A.M.C.

Captain CHEE JUAY POH, L.R.C.P.&S.Ed. Medical Officer, Singapore Volunteer Corps.

M.B.E. (Civil Division)

MARGARET KERR MENZIES ALEXANDER, M.B., Ch.B. Medical Superintendent, Christian Rainy Hospital, Todinart, Madras.

PUTHENVELIL MATHAI JOSEPH, M.B., B.S. Medical Officer, Seychelles Hospital, Seychelles.

JOHN ALAN BENNETT NICHOLSON, M.B., Ch.B., Colonial Medical Service. Medical Officer, Nigeria.

Mrs. MARGARET MARY SHEPHERD, M.B., Ch.B., late of Madras For medical services.

Captain MORTIMER LAWRENCE AXEN STEELE. First Class Military Assistant Surgeon, Indian Medical Department. Medical Officer, Victoria Memorial Hospital, and Quarantine Medical Officer, Bahrain and Officiating Residency Surgeon, Persian Gulf.

Bar to Kaisar-i-Hind Gold Medal

JEAN MURRAY ORKNEY, M.B., Ch.B. Chief Medical Officer, Women's Medical Service, India.

Kaisar-i-Hind Gold Medal

IVA NOEL GIBBINS, M.D. Medical Superintendent, Philadelphia American Hospital, Ambala City, Punjab.

JANE GRANT, M.B., Ch.B. Medical Officer, Church of Scotland Seoni, Central Provinces and Berar.

HERBERT KIRBY. Doctor-in-Charge, Jorhat Leper Colony, Jorhat P.O., Assam.

VICTOR CLOUGH RAMBO, M.D., F.A.C.S. Doctor-in-Charge, Mission Eye Hospital, Mungeli, Central Provinces and Berar.

BHAGWANT KISHORE SIKAND, M.B., B.S. Medical Superintendent, New Delhi Tuberculosis Clinic.

RONALD WILSON THOMAS, M.B., B.S. Medical Superintendent, Baptist Mission Hospital, Palwal, Gurgaon District, Punjab.

The Ministry of Transport points out that owners should in particular care to instruct doctors on Scale I ships to make arrangements for the drugs, sundries, and dressings to be replenished regularly, and for the proper maintenance of the surgical instruments and appliances. The medical cabinet of Scale II ships should be replenished by druggists according to the procedure explained Notice No. M.210, copies of which can be obtained at any mercantile marine office.

THE RED CROSS

WORK IN THE SECOND WORLD WAR

The Seventeenth International Red Cross Conference will be held at Stockholm in August, when a detailed report of war-time activities will be presented. As a preliminary a short account of the work of the International Committee has been published in Geneva under the title *Inter Arma Caritas*. On the day the war broke out the original four belligerents were informed that the International Committee had established the Central Information Agency contemplated under Article 79 of the Prisoners of War Convention signed in Geneva in 1929. During the war this Agency made out and filed 39 million record cards and forwarded 13 million letters. The longed-for parcel from home was received by prisoners on 36 million occasions. The workshop of the Agency was the Palais Electoral at Geneva, which was turned into a huge factory, with benches and business machines and crowds of workers, and there were 27 secondary workshops throughout Switzerland. One hint of the difficulty of tracing prisoners-of-war may be gathered from the statement that from a French village went a soldier named Jean Martin; to his mother there was only one Jean Martin in the world, but in the prisoner-of-war camps of Germany there were 15,000 Martins and 1,400 of them bore the Christian name of Jean.

The Red Cross Convention provides for the health of prisoners. Every prison camp must have its sick ward and every man the medical attention he requires. It is reported that in this respect the Convention was fairly generally observed. "Protected personnel"—persons engaged exclusively in attending wounded and sick—were picked out of the mass of prisoners and an endeavour made to secure their repatriation, but shortage of doctors and orderlies compelled their detention in camps to tend their compatriots, and the International Committee did its best to ensure that they were treated in accordance with the spirit of the Convention. The dispatch of medical relief had to be undertaken and there were frequent shortages of medicaments. Prostheses were in demand everywhere, but the greatest need was for dentures. With the help of instruments and appliances furnished by National Red Cross Societies, 64 dental surgeries were completely fitted out in the camps of Germany.

In the winter of 1941-2 thousands died every day in the Greek famine, and the health of the Greek people seemed to be threatened for a generation. The Turkish Red Crescent offered supplies, and supplies were also found in Switzerland and the Balkan countries. A chain of soup kitchens giving 800,000 helpings a day was improvised, and eventually a scheme was organized for monthly shipments from Canada to the Piraeus of 15,000 tons of wheat and 3,000 tons of other supplies, which were checked at every stage until their issue in the bakeries of the remotest Greek villages.

The difficulties behind this and much other work are not unduly stressed in the narrative. The achievement would have been on a much smaller scale but for the help of Switzerland. From the beginning to the end of the war the work of the International Committee cost 45 million Swiss francs, more than half of which was supplied by the Swiss Government and people. Even that immense sum, spent in six years, was equal only to the cost to all the belligerents of six hours of war. It is a fine record so far as Switzerland is concerned, and to Switzerland, too, fell the honour of providing at Geneva the one rent in the armoured curtain through which all this relief and succour passed. The greatest difficulty of all was the persistent reserve of the Soviet authorities with regard to the International Committee's offers of assistance. Letters sent to Moscow were unanswered, indirect negotiations led to no result, and millions of prisoners in Eastern Europe were deprived of the services which the Committee was anxious to render owing to the persistent silence—the unspoken "No"—of Russia.

A circular from the Ministry of Health requests hospital authorities to renew contracts for supplies and services due to expire before the "appointed day." They should be renewed on the basis and for the period which would have been adopted if no transfer under the Act was impending.

Reports of Societies

PLASMA PROTEIN FRACTIONS

At a meeting of the Section of Experimental Medicine of the Royal Society of Medicine on Dec. 9, 1947, Prof. H. P. HIMSWORTH presiding, the subject of plasma-protein fractions was introduced for discussion.

Dr. R. A. KERWICK, Director of the Biophysics Division, Lister Institute, said that during the last ten years considerable advances had been made in the knowledge of protein constitution of biological fluids and tissues. These advances had been due chiefly to the application of improved electrophoresis techniques introduced by Tiselius. The scale on which separation of proteins could be carried out by electrophoresis was still very limited, but in conjunction with classical methods for bulk fractionation of protein solutions the method had proved of great service.

By the electrophoretic examination of normal human plasma five components were originally distinguished—namely, albumin, alpha, beta, and gamma globulin, and fibrinogen, the globulins differing in charge but not markedly in molecular weight. Recent studies had indicated the existence of two alpha and two beta globulins. The amounts of the various proteins in normal human plasma were roughly as follows: albumin, 55%; the globulins, 38.5%; and fibrinogen, 6.5%.

After describing the system of fractionation of human plasma with ethanol at low temperature and of the ether fractionation system, Dr. Kerwick discussed the clinical application of plasma fractionation products. Perhaps the most versatile of the products of plasma fractionation were fibrinogen and thrombin. As the clotting time of fibrinogen-thrombin solutions could be accurately controlled, a liquid mixture could be applied locally which subsequently clotted. The tensile strength of fibrin clots increased with fibrinogen concentration, and solutions of fibrinogen up to ten times the corresponding concentration in plasma were readily attainable. The clots formed from such solutions had been used to suture severed nerves by a soldering type of process. Rather lower concentrations of fibrinogen provided, with thrombin, an excellent adhesive for the application and fixing of skin grafts, dispensing with the necessity for pressure dressings. Grafts fixed in this manner vascularized with extraordinary rapidity.

Fibrinogen preparations also contained a material which was effective in reducing the whole-blood clotting time in haemophilia from, say, 75 minutes to about 15 minutes. An injection of 10 ml. of a 2% solution would keep the clotting time at this level for about 48 hours. Fibrin films, resembling sheet cellophane in appearance, had been successfully used as a dural substitute with marked absence of adhesion. The film was eventually replaced by fresh dural growth.

Somewhat less purified fibrinogen solutions were utilized in the production of fibrin foam. By suitable devices these solutions were beaten to a finely dispersed foam which was set by adding thrombin and then dried from the frozen state. Such foams, if wetted again, tended to shrink rapidly, but this could be prevented by baking the dried foam at 130-170° C. The dried foam would absorb almost its own volume of thrombin solution, and was used in conjunction with this for local haemostasis in internal surgery. The foam was allowed to remain *in situ* following operative procedures, and eventually became organized into the tissue without scar formation.

It had been established that the antibodies in many infectious diseases were associated with the gamma globulin of normal adult plasma. Concentrates of this protein had been successfully utilized in the control of measles and might be useful in infective hepatitis. For measles intramuscular injections of up to 5 ml. were required. The use of similar concentrates prepared from convalescent-plasma pools from other infectious diseases—for example, mumps—had been examined. Purified albumin solutions containing 25 g./100 ml. had been satisfactory for transfusion in cases of shock and hypoproteinaemic oedema. Further research might indicate the usefulness clinically of other fractions derived from human plasma.

Electrophoretic Examination of Plasma

Dr. NICHOLAS H. MARTIN, of the Biochemical Laboratory at St. George's Hospital, also referred with appreciation to the electrophoretic technique elaborated by Tiselius, which had proved a convenient method of control in many fractionating processes. Electrophoresis might be defined as the phenomenon of migration of particles in a medium under the influence of a current applied through that medium. The protein mosaic of human plasma was analysable, as Dr. Kekwick had stated, into five main groups: albumins, the three globulins, and fibrinogen. The foetus and the newborn infant appeared to have a relative excess of gamma globulins. The electrophoretic patterns of human serum and plasma were not the patterns of pure protein but of the complexes of proteins with non-protein substances. The albumin fraction might contain carbohydrate and fatty acids; certain of the globulins might contain lipoids and steroids. In other words, electrophoretic homogeneity should never be considered to imply chemical homogeneity.

After discussing the comparison of electrophoretic with salting-out methods, Dr. Martin considered the protein pattern in disease processes. In diseases involving the liver parenchyma the pattern varied with the stage and extent of the disease. In the early stages of simple uncomplicated infective hepatitis there was a relative depression of the albumin, with increase in the gamma globulin. As the patient recovered, the albumin tended to revert to a normal level and the circulating gamma globulin level to drop. The gamma and beta globulins might show some change, notably between the 14th and 30th days, and it had been observed that their deviation from normal was greatest in those patients having a tendency to relapse. He showed an analysis of a simple uncomplicated case of infective hepatitis and pointed out the migration of the "bound" bilirubin in the serum with the alpha globulin. That the actual recovery of the circulating albumin might not be as rapid as superficial examination of the electrophoretic data would lead one to suppose was shown in a table in which the total circulating components had been calculated on two analyses in a moderately sick patient, the first towards the end of the first week, the second early in the fourth week, during the recovery phase. Whereas the level of the gamma globulin had fallen to normal limits, the total amount of circulating albumin was still 15% below normal in the fourth week. In established chronic liver damage analysis showed an absolute diminution in the circulating albumin with an increase in the gamma globulin, which might represent 30% of the total circulating protein.

It must not be imagined that the technique of electrophoresis as at present developed was to be used as a routine tool in diagnostic procedure—on a level with, for example, electroencephalography. Rather did its use lie in throwing light on the mechanism of existing procedure and in suggesting fresh approaches to the study of the fixed and circulating protein complexes in health and disease. It should not be used without an intelligent appreciation of its limitations. Electrophoretic homogeneity implied neither chemical homogeneity nor biological specificity; it was only one step—though a very important one—in the direction of the study of macromolecules.

ACUTE RHEUMATISM

At a meeting of the Devon and Exeter Medico-Chirurgical Society on Dec. 18 Prof. C. BRUCE PERRY gave an address on the aetiology and treatment of acute rheumatism.

Prof. Perry said that rheumatic heart disease accounted annually for 2% of all deaths and for 10% of all deaths under the age of 40. Haemolytic streptococci of no particular strain appeared to be the exciting cause, but the predisposing causes were at least as important. Scarletinal rheumatism, so-called, was identical with acute rheumatism. "Miniature relapses," only recognizable when the patient was under close observation and indicated perhaps merely by a rise in the sleeping pulse rate, were common. Epidemics of acute rheumatism followed epidemics of sore throat. The disease reached its peak in this country in December and January and was most prevalent in August and September. In New York it reached its peak in March. In the Arctic regions and in the Tropics it

was rare but not unknown. Children between the ages of 5 and 15 were most prone to the disease, and females were more commonly attacked than males, though carditis was often worse in the male and especially aortic endocarditis. There was a clear-cut social factor in the aetiology of acute rheumatism; it was commoner where there was poverty. The familial nature of the disease had often been noted, but it was difficult to balance the relative importance of heredity and environment. During the past 30 years there had been a decline in the incidence of this disease.

Treatment must be directed primarily against the carditis. Rest in bed, not flat but propped up on pillows, for at least six weeks was necessary. If there was any evidence, however slight, of continued infection the rest period must be prolonged for at least a month after all such evidence had disappeared. General hygienic measures must be adopted and local measures for the relief of joint pain. Salicylates in full doses, not necessarily combined with sodium bicarbonate, remained the best drug treatment. Penicillin and tonsillectomy were both valueless, and the results of the experimental prophylactic use of sulphonamides had not been impressive.

MEDICAL SOCIETY OF THE L.C.C. SERVICE CLINICAL MEETING

At a meeting of the Medical Society of the L.C.C. Service, at Lewisham Hospital on Dec. 4, 1947, Mr. J. GABE opened a discussion on the treatment of undescended testicle. He showed four cases illustrating the results of different methods of treatment. He considered that the operation should be done before the age of 16. Before operation was undertaken the diagnosis must be certain. Testicles often descended into the scrotum as late as the fourteenth year of life, and he thought that a course of "pregnyl" was of value in hastening the descent of a testicle round about puberty. In bilateral cases he had found the Bevin operation valuable, but in unilateral cases generally considered it better to do the Kectley-Torck operation. The chief difficulty in the operation was due to the shortness of the vessels, and great care was necessary to avoid dividing many vessels that atrophy of the testicle followed.

Thiouracil

Dr. GOTTLIEB read a short paper describing the results of treatment of 22 cases of thyrotoxicosis over the past three years by thiouracil and methyl thiouracil. Of these 22 cases four had eventually been treated by thyroidectomy owing to the occurrence of severe granulocytopenia. Of the remaining 18 patients, two died; one had had thyroidectomy performed three times, and the other had a severe aortic stenosis and, despite temporary improvement during treatment, died of congestive heart failure. All but three of the cases had been treated with methyl thiouracil. The dosage adopted was 200 mg. three times a day for three weeks while in hospital, then 200 mg. twice a day for two weeks as an out-patient, followed by a maintenance dose of 50 mg. once or twice a day for six months to one year. There had been an invariable improvement clinically, but all except two cases had relapsed within two to twelve months of stopping treatment. He had had two cases with no relapse for one year and fourteen months respectively, following cessation of treatment. During the treatment a weekly blood count was done, and eight patients in addition to the four already mentioned showed granulocytopenia; his criterion for granulocytopenia was 4,000 w.b.c. and 1,800 granulocytes. He considered that the only drug of any value for granulocytopenia or agranulocytosis was penicillin.

Congenital Intestinal Obstruction

Dr. SIMMONS, after referring to three cases of congenital intestinal obstruction which had been demonstrated, pointed out that this type of obstruction was said to occur in 1 case in 20,000, and was due to malrotation of the mid-gut, causing obstruction by pressure from without. The signs and symptoms were similar to cases of congenital hypertrophic pyloric stenosis, except that no tumour could be felt, the vomit was always bile-stained, and the vomiting started earlier in life.

relax smooth muscle spasm
within 3 minutes!

Smooth muscle spasm—the immediate cause of pain in renal colic and intermittent claudication—may be relaxed within *three minutes* by 'Depropanex' deproteinated pancreatic extract. Intramuscular injection with 'Depropanex' extract is a safe and effective method of controlling spasm caused by calculus, stricture or instrumentation, and also is efficiently employed to facilitate retrograde pyelography and ureteral dilatation.

'Depropanex' extract is a saline solution of a chemically-derived, protein-free nitrogenous fraction obtained from an acid-alcohol treatment of beef pancreas. It is physiologically free from insulin, acetylcholine and histamine. Supplied in 10-cc. vials. Informative literature forwarded on request.

'DEPROPANEX'

Deproteinated Pancreatic Extract

SHARP & DOHME LTD., HODDESDON, HERTS.

IN SOLID STAINLESS STEEL

These Bedpans and Kidney Bowls in mirror-polished solid stainless steel fulfil the most exacting demands of hospital authorities and staff. They provide comfort for the patient, are perfectly hygienic, extremely serviceable and light in weight.

The Bedpans are seamless, and have drainage holes in open half-roll lip.

The Kidney Bowls have open half-roll edge and are designed to nest, thus saving storage space. In 3 sizes—8" x 14" deep, 10" x 22" deep and 12" x 24" deep.

These are but two items from the extensive range of "Atec" Surgical and Medical Equipment in Solid Stainless Steel—the modern material for modern hospitals.

Write to Andrews Bros. (Bristol) Ltd., 6 Stainless House, Walcot Street, Bath.

'THIAZAMIDE'

BRAND

Sulphathiazole

Sulphathiazole is one of the most active sulphonamides at present available for the treatment of pneumococcal, meningococcal, gonococcal and haemolytic streptococcal infections—the sulphonamide of choice for the treatment of urinary tract infection, staphylococcal infections and gas gangrene: an effective chemotherapeutic agent in acute bacillary dysentery and in chancroid.

SOLUTHIAZOLE brand neutral soluble sulphathiazole derivative is recommended when parenteral administration is indicated

May & Baker's sulphathiazole preparations are protected by British Patent No. 533,495, which was granted on 24 May, 1946, jointly to May & Baker, Ltd., and Ciba, Ltd., of Basle.

Introducing

A NEW COMBINED

ANTIPEPTIC THERAPY

Following extensive work by the Warner Research Staff and after stringent clinical trials, we are pleased to announce the introduction of Gelusil*, a new combined antipeptic preparation and distinct advance in antacid therapy.

In recent years, ordinary aluminium hydroxide gels and magnesium trisilicate have deservedly taken the foremost place in the treatment of peptic ulcer. Used separately, they have many advantages — and some disadvantages. Gelusil combines, in each tablet, the undoubted therapeutic virtues of both drugs while obviating their drawbacks. This new approach to antipeptic treatment is made possible by the unique properties of a specially processed, partially dehydrated aluminium hydroxide gel having all the essential virtues of ordinary alumina and none of its defects.

Literature and samples will be supplied on request.

Each tablet contains approximately 7½ grains
Magnesium Trisilicate and partially dehydrated
Aluminium Hydroxide Gel corresponding to 4
grains Aluminium Hydrate.

GELUSIL

Ultra-Violet Therapy

Lumsden Portable Ultra-Violet Lamps are unique because in a small compact case is housed a high pressure Quartz Burner with sufficient output for all professional needs, yet so simple to operate that it can be prescribed for a patient's use.

They are Lamps which can be safely carried in a car and take up little space. The Burner has an excellent spectrum range.

Full information can be obtained from the LUMSDEN LAMP CO., 258, MILLBURN, ALMONDBANK, PERTH.

LUMSDEN SUN LAMP

O T I T I S M E D I A

DECONGESTION OSMOSIS WITH REMEDIAL ANALGESIA

DECONGESTION SUCCESSFULLY ACHIEVED by the addition of Ephedrine Sulphate which, acting in synergy with the other ingredients, produces shrinkage of the mucosa, promotes drainage from the middle ear and a rapid control of pain. The bactericidal constituents of Auralgicin cover a wide range of micro-organisms, including those likely to be present in otitis media, thus avoiding the danger of masking.

AURALGICIN

DDA

(BENGER)

Each ml. contains :

Phenazonum	0.050 g.
Papaveretum	0.025 g.
EPHEDRINE SULPH.	0.010 g.
Chlorbutol	0.010 g.
Pot. Hydroxyquinolin Sulph.	0.001 g.

Glycer ad 1 ml.

FOR EXTERNAL APPLICATION

BENGER'S LTD. HOLMES CHAPEL, CHESHIRE

Mr. JEMSON, who had operated on the three cases, pointed out that the faulty rotation of the mid-gut left adhesions attaching the transverse colon to the duodenum. Referring to the investigations of Ladd and others in America, he said that the best operation in these cases was to divide the adhesions between the colon and the right upper quadrant of the abdomen, and push the whole transverse colon and ascending colon over to the left. This resulted in a broader base being given to the mesentery of the small intestine, which in these cases was practically absent, and thus helped to prevent the later occurrence of the volvulus. Mr. TANNER said that this condition might persist into adult life; he had had two such cases. Simple division of the adhesions was not adequate for cure in adults; a short-circuiting anastomosis was needed.

Correspondence

Censorship

SIR.—Mr. J. Johnston Abraham (Dec. 27, 1947, p. 1053) calls attention to a matter of first-rate importance not merely to the medical profession but to the nation as a whole—namely, will the doctor be free to write and publish under the new Health Act or will he not? It seems extremely doubtful if he will. The following question was asked in the House by Mr. I. J. Pitman:

"What are the general principles under which State employees are allowed or forbidden for payment to write for publication on technical matter peculiar to their specialization; and what differences are there in the particular cases of the Royal Air Force and the Air Ministry, the National Coal Board and decentralized coal units, and the medical services and the Ministry of Health when the appointed day is past?"

Mr. W. Glenvil Hall, Financial Secretary to the Treasury, replied on Nov. 6:

"A Crown servant must obtain the consent of the head of his Department for the publication of any work the subject matter of which is connected with his official duties or those of other public servants. In cases where the work is considered to owe its value exclusively to the author's ability and research, no special financial arrangements are made. In other cases the Government may either arrange for official publication or stipulate that copies should be supplied for the public service at a special rate.

"These rules apply to the Royal Air Force, the Air Ministry, and the Ministry of Health. I have no information about the arrangements in the coal industry, which are a matter for the National Coal Board itself. I understand that no rules have yet been made for employees of the new bodies set up under the National Health Service Act."

From this reply the position of the doctor to be employed under the National Health Service Act is somewhat obscure. If he is classified as a Crown servant then he will apparently rarely, if ever, be entirely free to write, and there is considerable danger that regulations would in due course be laid down by the Treasury for doctors serving under the National Health Service Act, on lines similar to those applying to the Civil and other services. Were such regulations to be applied the present freedom of expression of medical opinion would cease. It therefore appears most urgent that the position should be clarified.—I am, etc.,

London W.C.1.

R. F. WEST,
Chairman, Medical Group of the
Publishers Association

National Health Service

SIR.—I append five subjects for G.P.s to consider.

Remuneration.—(a) Basic salary opens door to a full-time salaried service, disapproved by the Spens Committee. (b) Both salary and capitation rate have never been discussed nor agreed to. They can be altered by the Minister whenever he considers necessary and certainly in two years. (c) Capitation rate for 1,000 patients is 21s. 1d.; capitation rate for 4,000 patients is 16s. 8d. This must act as a discouragement to men working in an industrial district, where private practice is likely to be scarce.

Compensation.—(a) £66,000,000 computed in 1938 is probably not adequate in 1948. (b) It may prove impossible (anyway it will take years) to estimate what any one practice should receive, as all practices have to be investigated before any one can be valued. (c) The Minister's decision that a doctor not joining on the appointed day shall forfeit his claim to compensation savours of bribery and intimidation.

Midwifery.—In England and Wales all practitioners must satisfy a local committee that they are adequately qualified to practise midwifery within the Service.

Direction.—The Minister states that a doctor is free to practise where he chooses. This immediately becomes false once the Service is established. Local committees will decide whether an additional doctor may practise in their area and will have the disposal of all Service practices and houses.

Control.—The Minister retains power to appoint all chairmen of all committees for all time, and ultimately to approve all members lay and medical. Under these circumstances what hope is there of amending the Act (save favourably to the Ministry) once the Service is started?

Health Centres are in abeyance. Doctors and their unfortunate wives will be expected to make good the rash promises made by the Ministry. In my opinion G.P.s would be well advised to say "No" to working the unamended Act.—I am, etc.,

Birmingham.

WM. WATSON NEWTON.

SIR.—Surely the time for clear thinking has now arrived; we must face facts, and face them unflinchingly. It is obvious that the Minister intends, for political reasons, to have a full salaried service—and that within two years. If we sign on the dotted line to one set-up of regulations, it will be well within his power to alter our remuneration and/or our method of payment at any time he likes. Once we sign we are for ever in the clutches of the Minister, and the freedom of the doctor and patient will be gone for ever. Partnerships the Minister pretends to welcome but obviously intends to destroy, the present Act making all our old partnership deeds quite unworkable. Ministers dislike partnerships; groups tied together by many bonds are always stronger than the same people existing as separate entities.

There are numerous young men in the profession who see in State control some semblance of personal security. I would beg them to realize that their "Yea" for the questionable privilege of doubtful security may well remove from the people of their country almost the last shred of real freedom which still remains to them.

The B.M.A. has had a very difficult task and has lately done it with courage, but many think, as I do, that had their earlier attitude to the Government been firmer they would have received greater support from the profession and more respect from politicians. At all events, it is not too late for them to put the profession on its guard, and when the time for the plebiscite comes let us have no more ambiguity but rather a strong pointer in the direction of freedom, so that they may be blessed not only by the profession as a whole but by all thinking men and women as the champions of independence and liberty.—I am, etc.,

Wokingham, Berks.

RALPH ROSE.

SIR.—I entirely agree with Dr. A. F. Chalkley's appeal for plain speaking (*Supplement*, Dec. 13, 1947, p. 139) and for freedom. Let us have the courage of our convictions. Very few in our profession really want State medicine, but they are afraid to back their opinions with action or even to state them clearly. Why? I believe it is due to four things—viz.:

(1) Muddled thinking. One often hears it said, "Probably the Ministry knows what it is about." Yes, but what is it about? Certainly not the highest good of the greatest number. It is out, "by the deadly method of one by one," for State Socialism, which is State monopoly of all the professions, beginning with medicine. Ahead lies supreme political and economic bureaucracy, with slavery for everyone else.

(2) Fear of insecurity. Alas, this un-English craving for security has grown on us. Safety first is a very poor motto, and would never have won the war. Too many younger members of our profession are terribly afraid of insecurity and seem to prefer safety to freedom itself. As an older friend said

to me. "We had the same difficulties and chances when we came out of the Services in 1919. Why can't the modern young man do as we did?"

(3) The habit of obedience. The tragic result of our patriotic obedience during the war has made us all in danger of losing our sense of individual initiative and responsibility. And again it is our younger members who are far too ready to toe the line and become yes-men. Let them have the courage to say no.

(4) Plain disregard of facts. It is we who have the whip hand, not the Minister of Health. He can do nothing without us whatever he may say. It is we who are in the strong position now, but we are in the middle of a terrific battle, and if we fail we betray the side of freedom in every department of our life in England and the freedom of those who come after us. Let us realize this temporary Minister of Health is only like a very difficult patient determined to get his own way by any means. Let us be more determined ourselves not to be bullied, browbeaten, or fooled. The medical profession has with immense patience tried its best to get Mr. Bevan to co-operate. He has not moved an inch. He never had the slightest intention of co-operating. Mr. Bevan is an extremely ambitious politician. He has failed miserably over his vaunted 1945 housing schemes. Now he is trying desperately by very clever alternations of pay-packet promises, bluster, and pretended care for the health of the people to bolster up his own failing prestige. Let us call his gigantic bluff! Finally, let us remember this all-important fact. Within a fairly short time, possibly this year, this totalitarian Socialist Government will be superseded by a really progressive one. Then we shall get a Health Bill we can all support freely.

The leading article "Mr. Bevan's Gloss" (Dec. 27, 1947, p. 1037) puts the case very fairly and clearly. Now it is up to each one of us individually. Let us remember our tradition of courage, independence, and self-sacrifice. Let us accept our great responsibility to our nation, our patients, and our profession, and for their sakes as well as our own say in the coming plebiscite a categorical "No, we will not serve in any way under the present Act."—I am, etc.,

London, S.W.1

SYBIL TREMELLEN.

SIR,—May I try to answer a fear which I have heard expressed? "I do not want to join the Service, but I have no alternative. I must support my wife and family." This line would inevitably ensure only a small minority of opposition to the Minister. "It will be all right if we get a good majority." We shall get no majority if we cannot each decide alone to do what we think right. The hope for a good majority shifts the responsibility from ourself to our professional neighbours.

To answer the question, If the worst comes, and I find myself alone outside the Service, how can I earn my living?—First, my panel and contract patients will unwillingly and complainingly overcrowd the waiting-rooms of doctors they have not hitherto wanted to choose. Then some few of my "private", patients will continue to support me. Soon after this my neighbours' duchesses will refuse to wait in their crowded rooms and will transfer to me. Then there are all the regular "nuisances" who are never patient or amenable to the discipline of regular times for sending their "urgent" messages. They will soon find I have time to give them. Of course I shall have to make changes in my hours and find an entirely new and experimental scale of fees, but still, if the worst comes, it will be possible to make a living—perhaps a good one. And if the worst does not come, and we all stay outside together until the Minister learns that "sincere co-operation" entails give as well as take, then the best will have happened.—I am, etc.,

Greenham, Berks.

H. D. FORBES FRASER.

SIR,—At present we enjoy freedom and owe allegiance to none save our patients. The country has a good medical service, but it can be improved upon with the co-operation of the Government. In working for improvement we are not concerned with our own political beliefs or the particular form of government which happens to be in power. Governments will come and go, but medical progress must be directed towards a fixed ideal, undisturbed or hampered perhaps by government, but certainly not influenced by them.

Since the Socialist Government came into power the necessity of clinging stubbornly to our freedom has become more and more obvious. Socialist authorities have tried to force doctors into trade unions. Why should a professional man be required to associate himself with an organization originally intended for the protection of employees against employers, and legitimately concerned only with industrial matters? When one considers the way in which trade unions have become increasingly powerful, and increasingly preoccupied with political issues—a sphere incidentally in which they are quite undemocratic—then their danger is obvious. Since the inception of the present Government we must all have received communications urging us to join a certain medical union affiliated to the T.U.C. This union disclaims any political affinities and thus, in my opinion, denies the only logical reason for its existence.

The present Government has already given rise to doubts regarding its moral integrity; already we have been given instances where materialistic progress has been the excuse for violation of moral principles. I believe that in spite of the honeyed words of Mr. Bevan he seeks to use the National Health Service Act as a means to a political end—i.e., the confusion and gradual enslavement of a profession whose political views are predominantly anti-Socialist.

It would be well to take heed of Mr. Churchill's pre-election warning of the dangers of totalitarianism in a Socialist state. If we allow ourselves to be lured by Socialist bait into captivity, then we are unworthy of our great heritage and will be cursed by many generations of medical men to come. Politicians can play a clever and often underhand game to gain their own ends, and in dealing with them we must unite in rejecting any plan of any government which involves even the remotest danger of encroachment upon our liberty, and in addition avoid being lured into any suspicious "medical" organizations. "Necessity is the plea for every infringement of human freedom. It is the argument of tyrants; it is the creed of slaves."—I am, etc.,

Edinburgh.

W. B. LAING.

SIR.—Two years ago the B.M.A. first published what it chose to call the seven principles of the profession in its relation to the new National Health Service Act. The leading article in the issue of Dec. 20, 1947 (p. 1002), concludes with the following paragraph: "Preoccupation with financial and other details . . . must not obscure the main issue which the medical profession now has to face. This issue is summed up in the first of the principles enunciated by the Negotiating Committee exactly two years ago." In two years' time the seven principles, like the ten little nigger boys, have been reduced to one—"the main issue." What about the other six principles? Are they no longer important, or (as I suspect and believe) does the Negotiating Committee agree with the Minister that the Act does no longer conflict with these principles?

Let us examine the first principle, which reads: "The medical profession is, in the public interest, opposed to any form of service which leads directly or indirectly to the profession as a whole becoming full-time salaried servants of the State or local authorities." It is high time that we discarded such phrases as "in the public interest," "desiring to secure for the people the best possible health services," "grave hardship to the patients," as they are mere cant and humbug. Let us at least be honest and state that what we are really studying is our own interest first, last, and always.

Read the Negotiating Committee's case, and especially that part of the case which deals with general practice. This takes up some six pages of the document, and, of these, three pages are taken up with arguments about existing partnership agreements and partnerships after the appointed day. What is this to do with the public interest and how can this "secure for the people the best possible health service"? I repeat that this is mere cant and humbug, and that the first principle ought now to read, "The medical profession is in its own interest opposed, etc."

The main point at issue between the Negotiating Committee and the Minister at present is the question of buying and selling of practices and the mode of payment by salary or capitation fee. The leading article states that the Minister "refuses to meet the profession's strongly rooted objection to a basic salary." May I remind you of a document which has been discreetly pigeon-holed by the leaders of the B.M.A. since 1944. I refer to the questionnaire issued in March, 1944, by the B.M.A., the replies to which were published in the *Supplement* on Aug. 5, 1944 (p. 25). These replies give the only definite figures available on the question of payment

Question 18 (para. 29) asks, "If a doctor is not working in a Health Centre, but in 'separate' practice, how should he be remunerated in a National Health Service?" Reply:

Description of Group	Replies in Percentages		
	Salary	Small Basic Salary plus Capitation Fees	Capitation Fees
All General practitioners	15 12	35 28	44 55

I have not included all groups. It is fair to assume that those who voted for salary only, if given a second choice, would prefer a small basic salary plus capitation fee to payment by capitation fee alone. This gives us a figure in all groups of 50% who are not in favour of payment by capitation fee only. In the general-practitioner group the figure is 40% not in favour of payment by capitation fee alone, but the number of general practitioners who are in favour of payment by capitation fee alone is only 55%, therefore there must be 5% of general practitioners who do not care how they are paid and did not vote. From these figures I fail to see "the profession's strongly rooted objection to the basic salary."

The next point I wish to make concerns the statement in the leading article that the Minister refuses to give in on the question of "the retention of the custom of buying and selling practices, which general practitioners as a whole regard as essential to their freedom." Question 22 (para. 23) asks, "Do you think that the sale and purchase of publicly remunerated practices should continue or cease?" Reply:

Description of Group	Replies in Percentages		
	Continue	Cease	Don't Know
All General practitioners	33 44	52 44	13 10

Question 23 (para. 34) asks, "Should the principle that all general practices may be sold and purchased be maintained or abandoned, on the assumption that adequate compensation is paid to existing owners?" Reply:

Description of Group	Replies in Percentages		
	Maintained	Abandoned	Don't Know
All General practitioners	33 39	56 53	10 6

These figures definitely show that general practitioners as a whole do not regard the custom of buying and selling practices essential to their freedom.

It is interesting to note that the leading article in the current *Lancet* queries whether the ownership of goodwill is really a vital principle. The figures I have quoted cover "the main issue" as explained by the *B.M.J.* leading article. Will I enter the new Health Service in July, 1948? You bet I will!—I am, etc.,

Machynlleth, Mont.

DAN E. DAVIES.

SIR,—In reference to the late discussions with the Minister, it is quite evident that he will give way on nothing of fundamental importance unless he be forced to, and that if we are foolish enough to "walk into his parlour" when he asks us we shall become medical servants under a totalitarian central authority and be lost, body and soul, as far as freedom is concerned and be obliged to bow the knee to whatever that authority likes to order—or else!

The burning question now is, What are we to do? We are to have another plebiscite. May I suggest that the questionnaire be couched in the simplest and most unequivocal form possible, such as the following: "Do you wish to serve under the new Act as it is? If not, are you willing to refuse to do so if a percentage of doctors, sufficient to enable the B.M.A. to deliver an ultimatum of refusal to the Minister, also agrees to do so?"—for I am convinced that, unless the B.M.A. be armed with a sufficient percentage of Noes or, better, a sufficient number of names, and be authorized to present them to the Minister and so force him to amend the Act, we might as well cave in at once. If nothing effective like this can be done I think it almost certain that a large number of general practitioners, loath as they are to join the

Service, will, when presented individually by the Minister with a demand for decision and not knowing what the other fellows are going to do, not feel themselves able to refuse to join the Service, simply from fear of subsequent starvation.—I am, etc.,

Thame, Oxon.

C. H. BARBER.

SIR,—It is only natural that many practitioners, especially those younger men with heavy financial commitments, should feel anxious regarding their position did the profession decide against accepting service under the new health scheme. I am confident that the B.M.A. has not overlooked such a contingency, but a definite promise that they would be able to survive would help them materially in coming to a decision. They would also feel happier in refusing service could they be assured that the Englishman's word would still be his bond.—I am, etc.,

St. Columb, Cornwall.

G. MELCHOIR TORRANCE.

SIR,—After reading Sections 35 and 36 and the negotiations and counsel's comments thereon one comes to the conclusion that whoever drafted these Sections—and others in the Act—must have been suffering from a brain storm or similar kind of mental derangement. There is only one logical way of dealing with the purchase of practices by the State—buy all practices at the same time at similar terms and tell us when we are negotiating what price we get—for example, 1, 1½, or 2 years' purchase on the last 3 or 5 years' gross receipts. The 1939 values are useless owing to the advance in fees we have been forced to make to compensate for the increased costs of living and running a practice. So far as partnership agreements are concerned the Act should contain a clause rendering these void on day of purchase, and each partner would get a share of the price received for the partnership according to his share of the practice. In the case of one partner not joining the Service his share of the partnership would not be purchased and he would automatically become a private practitioner and be free from the partnership.

We were given to understand that the new Health Service was to be an advance step, but the Act as it now stands is in every way the reverse. Group practice is definitely discouraged when it ought to be encouraged. There is no provision for encouragement of post-graduate study or taking higher degrees. Holidays and reasonable hours of work are not in the picture, in spite of the fact that these would give practitioners a reasonable chance to keep fit so as to do better work. The only object of the whole Act is to place the medical profession under the thumb of the Minister of Health and finally to turn us into puppets to dance to any tune he cares to play.

The capitation fee proposed is far too small, and any figure under 25s. per head should be definitely refused. As the Act stands at the moment it will only encourage a mad rush to get as many patients on to each panel, by fair means or foul, and then to do as little work as possible for them.

There have been several schemes devised in the past for a service which would be a great advance on our present system. Let us cease trying to negotiate with the present Minister, who evidently does not understand what negotiating means, and turn down the Act completely. Then let the profession get down to the job of providing a really up-to-date and workable scheme and offer to put it into practice. We have the power to do this now. Let us at last show a united front.—I am, etc.,

Wetherby, Yorks.

S. T. PYBUS.

Payment of Hospital Staff

SIR,—At a meeting of the Marylebone Division of the B.M.A. held on Dec. 30 to consider the attitude of the profession to the National Health Service one of the speakers criticized the medical staffs of several of the London teaching hospitals for accepting payment for their hospital services. University College Hospital was one of those named, and the implication offered by the speaker seemed to be that the medical staff had as a body thereby declared their intention to accept service under the N.H.S. irrespective of the result of the plebiscite shortly to be held by the B.M.A.

This implication, if intended, has no substance. The facts are that the governing body of the hospital made an offer to the individual members of the part-time honorary medical staff of a payment for their hospital services during the year 1947.

Some accepted and some declined. Those who accepted doubtless had in mind the advice given in the joint letter from the B.H.A. and B.M.A. dated Aug. 9, 1947. This payment was offered entirely without prejudice to the future of the staff under the N.H.S., and neither the acceptance nor the refusal of that payment carried with it any obligation on the individual, declared or implied, either to accept or to refuse service under the N.H.S. in July next.—I am, etc.,

S. COCHRANE SHANKS,
Dean, University College Hospital Medical School.

The Coming Plebiscite

SIR.—The plebiscite form will soon be in our hands and our answer will determine the future of medicine. One point that is giving concern to those who have in mind to say "No" is the question of support if a sufficient majority of the profession should be of that mind. Could a clause be inserted in the plebiscite form asking if those who will vote "Yes" are prepared to give an undertaking that in the event of their being in the minority they will loyally support their "No" brethren, so that there will be no question should the vote go to the "Yes" side the others will conform.—I am, etc.,

Mumbles, Swansea.

J. BURGESS JAMES.

SIR.—Now that the results of negotiations with the Minister of Health are made known to us, we the doctors are to be asked again to vote "Yes" or "No" to the Health Act. Since the Minister has again refused point blank to amend this Act in any particular, there is nothing new to vote on. Why, then, are we asked to vote again? Is it because it is hoped that since the last plebiscite we have lowered our standards? Otherwise there is no point in having another plebiscite.—I am, etc.,

Leigh-on-Sea, Essex.

A. H. LEVERS.

Remuneration in N.H.S.

SIR.—It is probable that only a very small minority of general practitioners favour a salary, even a basic one, but there must be a considerable number who hesitate to refuse because of their own limited resources. Could not the B.M.A. publish a scheme, at least in outline, designed to meet their difficulties? That this would be worth while is illustrated by the experience of a young doctor who wrote to the B.M.A. for advice. He was referred to a commercial house, whose terms proved to be as follows: Interest should be at 4%; he should take out a life insurance, and he should repay the capital at 12% per annum—£30 per quarter on £1,000—in ten years. So for £1,000 he would have to pay £1,200 spread over only ten years, as well as 4% interest and a life insurance premium. Obviously such terms could not compete with the offer of the Minister.

It has been suggested that to a man of good character and sound health the B.M.A. might lend or guarantee a suitable sum of money free of interest for a limited period, repayment of capital to begin at the end of that period at a rate varying with individual circumstances.

With respect to the plebiscite, it seems probable that very useful information could be obtained by taking account of district voting. It is likely that a larger number of districts would be for or against acceptance than would appear from the mass voting. A significant difference, especially if generally the majorities in those districts were large, surely would be very important.—I am, etc.,

Beckenham, Kent.

W. MAXWELL PENNY.

General Practitioners and the Basic Salary

SIR.—May I be permitted to ask what percentage of general practitioners in active practice has "a strongly rooted objection to a basic salary"? Who gave the Negotiating Committee the authority to say this and is the statement true? If the profession has this strongly rooted objection, how can the payment of a capitation fee of 15s. 2d. to 18s. possibly recompense him for the loss of private fees? Is it reasonable to suppose that a private fee-paying patient who can retain the services of the same practitioner will continue to pay private fees and a State contribution as well?

It may seem fantastic, but no one is going to pay any more than is necessary if it can be avoided; and who will pay £1 1s.

if the same service can be obtained from the same source for 5s. or less, even if it can be well afforded? Therefore, so far as I can see, private patients will soon be converted to so-called "public patients." Neither a £300 basic salary nor a capitation fee of 18s. (or less) can possibly compensate for the loss, which is inevitable. The result, so far as I can see, will be that in the smaller and more especially rural practices, where I should say two-thirds of the annual income is derived from private fees, a financial catastrophe faces the practitioner. I could give figures to prove my statement and I expect many more could do so as well.—I am, etc.,

Callander, Perthshire.

F. C. M. McILWICK.

** In para. 34 of the Negotiating Committee's document (Supplement, Dec. 20, 1947, p. 146) the Committee advocate remuneration by capitation payment and states its opposition to payment by a salary, basic or other. This is in accordance with the first of the "Principles of the Profession" enunciated by the Negotiating Committee and published in the *Journal* of March 30, 1946 (p. 468). The members of the Negotiating Committee were elected by the B.M.A., the Royal Colleges, the Royal Scottish Medical Corporations, the Society of Medical Officers of Health, the Medical Women's Federation, and the Society of Apothecaries, and represent their views. At the Special Representative Meeting held on May 1 and 2, 1947 (Supplement, May 11, 1946, p. 126), the motion declaring for capitation fee and against salary or part salary was carried by 209 votes to 8.—ED., B.M.J.

Representation on the Negotiating Committee

SIR.—In your leading article (Dec. 20, 1947, p. 1002) you state that "the Negotiating Committee, it is well to point out is representative of all phases of professional life." May I point out that this is not quite correct, since a small but no insignificant group has not, to my knowledge, been represented on the Negotiating Committee. I refer to the medically qualified preclinical teachers, whose case appears not to have received consideration and is therefore likely to go by default. It is not too late to rectify the omission by adding to the Negotiating Committee a representative of this group.—I am, etc.,

Department of Anatomy, The University,
Bristol.

J. M. YORRIV.

Leakage

SIR.—I wonder if any member of Council or of our discussions committee has read an article on p. 5 of the *Tribune* of Dec. 12? It is headed "Bevan and the Doctors," and to say that I was shocked when it was brought to my notice by a colleague is to put it mildly. It viciously attacks the B.M.A. and the Negotiating Committee (*sic*), says that if they ever hoped to gain concessions or amendments to the Act or postponement of the appointed day they must now be bitterly disappointed, and then goes on to *enumerate nearly every point* in the Minister's reply to our case. It exults in his refusal to concede one iota, in his determination to bring in the Service on the appointed day with "the means at his disposal," and particularly in his absolute refusal to give in over direction of doctors or on the matter of the sale and purchase of practice. It says that the B.M.A. has become the instrument of Conservative policy, but that it will not succeed in preventing the establishment of a *Socialist* medical service. It then goes on to suggest that any hope that the B.M.A. has of persuading doctors to refuse to enter the Service will fall to the ground when the enticing financial terms—basic salary, plus a capitation fee of "not less than" 17s. 6d. and "generous" compensation—are circulated within a few days to every doctor in the country.

At the Panel Conference in October I had occasion to say that I felt that the seven months of "discussions" (what a irony!) had been a period of phoney peace during which our wily opponent had had leisure to perfect his plans for a blitzkrieg, and this unsavoury *Tribune* business has confirmed me in that opinion.

Surely, then, the time has now arrived for all medical members of executive councils, regional boards, *et hoc genus omne* to resign; and I should like to suggest that this be done nationally on a set day, and that at the same time it be arranged

for insurance practitioners to put in notices of resignation from the N.H.I. service and for members of National Service and Ministry of Pensions Medical Boards to do likewise. This would serve to show this dictator-minded Minister that we are by no means disposed to walk into his parlour or to succumb to his ruthless threat of force, and that we at last realize that we can place no trust whatever in his word. Having marked our disapproval in this unmistakable fashion, we could then settle down with quieter minds to hold our plebiscite, and to get ready for the inevitable conflict.—I am, etc.,

Wolverhampton.

A. VICTOR RUSSELL.

Sulphamerazine Treatment of Pneumonia in Adults

SIR,—The results obtained by Drs. H. Joules and S. D. V. Weller (*Journal*, Dec. 13, 1947, p. 947) are interesting, but we are told little about the type of pneumonia. Radiological details and detailed leucocyte counts are not given, and apparently the pneumococcus was isolated in only 53 cases—28% of the total series. There is no mention of blood cultures in the severe cases. The satisfactory response with such small doses of sulphamerazine would appear to be due in part to the mildness of many of the infections.

Sulphamerazine's easy absorption and slow excretion are noted, but no mention is made of the fact that in the blood 80% is bound to the globulin fraction of the plasma—i.e., only 20% of the blood sulphamerazine is available for antibacterial action (Heffner, 1945). Hence the importance of moderately large doses of the order of 30 g. over 4 to 5 days in order to maintain, as Genecin *et al.* (1945) have found, blood levels of 12 to 16 mg. per 100 ml. In a small personal series of 68 African patients suffering from lobar pneumonia treated with this drug (Johnston, 1947) the advisability of this latter dosage was confirmed. Sulphamerazine is a valuable drug in the treatment of pneumonia, but it should be given in adequate doses, bearing in mind also the recent warning limitations concerning penicillin.—I am, etc.,

Aberdeen.

R. N. JOHNSTON.

SIR,—The article by Drs. Horace Joules and S. D. V. Weller on the sulphamerazine treatment of pneumonia in adults (Dec. 13, 1947, p. 947) attracted my particular interest this week, as we have under treatment at the present moment our second case of anuria in a male, due to obstruction of the lower end of both ureters by concretions of sulphamerazine crystals.

I had in mind to publish full clinical details of these two cases at a later date when full recovery has occurred. It seems timely enough, however, to bring to the notice of your readers that sulphamerazine is capable of producing anuria even when used in reasonable doses, for in both cases to be reported the patients had no more than 1 g. four-hourly for less than a week. This is more than advised by Drs. Joules and Weller, but nevertheless not excessive. Both patients were instructed to take large quantities of fluid, but were not given alkalis. Fortunately, the obstruction was quite easily overcome by ureteric catheterization and lavage with a 5% solution of sodium bicarbonate.

Sulphamerazine is used far less commonly than sulphamezathine, yet so far in our district we have no knowledge of calculus having occurred from sulphamezathine, and it would appear, therefore, that if the therapeutic effects of the latter compound are as good as those of sulphamerazine the British drug is the safer of the two.—I am, etc.,

Chelmsford, Essex.

M. D. SHEPPARD.

Penicillin in Scarlet Fever

SIR,—Your annotation on penicillin in scarlet fever (Dec. 6, 1947, p. 915) is based solely on the work of Meads *et al.* (1945) and Jennings and de Lamater (1947) and ignores every publication by British workers and many important American papers. The penicillin treatment of infections of the oral cavity and upper respiratory tract has followed a logical sequence since Garrod (1944) stressed the sensitivity of a wide range of mouth organisms. The role of penicillin applied locally to the mouth has been investigated by numerous workers. MacGregor and

Long (1944) indicated the probable value and limitations of penicillin pastilles in acute and chronic streptococcal tonsillitis. Mowlem (1944) drew attention to the extraneous organisms that invade the mouth during penicillin treatment.

Vollum and Wilson (1945) and MacGregor and Long (1945) discussed the method of spread of drugs in the oral cavity. Symons (1945, 1946), Archer (1945), Dodds (1946), Christie and Preston (1946), Long (1946a, b; 1947a) in this country, and Karelitz *et al.* (1947) in America, have discussed the role of penicillin in the treatment of diphtheria and have provided much information on the effect of the drug on secondary infection. Long (1946a, b; 1947a, b) has compared the effects of local and systemic penicillin on the flora of the mouth and upper respiratory tract and has suggested the need for a dosage of 1,000,000 units a day for three days. Rantz *et al.* (1947) noted that "post-streptococcal disorders were not observed in a small group of patients who received 500,000 to 1,000,000 units of penicillin in 80 hours."

I suggest that to exclude all reference to these publications is to detract from the value of your contribution. For instance, the statement that "the three risks of scarlet fever, then, are the primary toxæmia, the early endogenous invasion, and the late exogenous reinfection, and no one treatment is likely to combat all three" is not compatible with published information on the subject. It would seem to me that if the pathogens can be eliminated in a matter of hours in the early stages of the disease the toxæmia will be halted, local spread prevented, and the patient will be rendered non-infectious.

The work of Jennings and de Lamater from which your contributor obtains most of his information indicated quite clearly that, in spite of a dosage of 400,000 units daily, pathogens were not eliminated from the throat, and complications due to local spread of infection occurred. The obvious conclusion is that this dosage was too small. Since it would be insufficient to remove the highly penicillin-sensitive organisms from the gum pockets it could scarcely be expected to remove the more resistant streptococci from the tonsillar crypts, while the risk of rendering organisms penicillin-resistant by under-treatment cannot be ignored.

It would be unwise to predict the future of penicillin in the treatment of scarlet fever, diphtheria, acute haemolytic streptococcal tonsillitis, and the associated carrier states (for they are one problem, not many). It is probable that when we know what dosage of penicillin will eliminate all pathogens from the oral cavity and upper respiratory tract in the minimum time, and if we can show that in the case of infections associated with toxæmia the level of antitoxin reaches a lower titre in the blood of those treated with penicillin than in a control group receiving no penicillin, we will be on the way towards the solution of our problem.—I am, etc.,

London, W.C.1.

Diet and the Nation's Health

SIR,—It is surely time we had some hard facts about the nutritional position to-day, instead of the flood of opinion—usually pessimistic and more or less uninformed, misinformed, or merely malicious—which is obtaining headlines in the public press, and even finds a platform in your own columns.

The speakers for the motion at the recent Hunterian Society debate were doubtless convinced of the worth of their opinions, but, if your report (Nov. 29, 1947, p. 882) is substantially correct, Sir Jack Drummond spoke nothing less than the truth when he claimed that "no concrete facts had been brought forward to support the view that there had been deterioration

of health as a result of diet." Dr. F. M. R. Walshe's scathing retort (Dec. 13, 1947, p. 971) does nothing to persuade me otherwise; for even a "clinical opinion" should be based on relevant fact.

Dr. G. T. Mills's letter (Dec. 6, 1947, p. 926) has a spurious air of objectivity. Since anyone can calculate the food value of rationed foods and make a reasonable estimate for points foods, his figures for these items may be accepted at their face value. But on what basis was his list of unrationed foods compiled? Either he conjured up these foods and their quantities out of an unspecified "general experience"—always a hazardous, and in this case unjustifiable, procedure—or he based them on actual observation of definite "cases" by a definite method. If the latter I should like to know how he selected his cases and what his technique was. Without this information, I am entitled to assert that his figures prove absolutely nothing. Incidentally, Dr. Mills compares a presumptive total home diet for an adult consumer receiving no priority foods with the reputed consumption per head of the whole population—including women and children as well as the men, heavy workers as well as sedentary workers, invalids as well as the healthy, and so on. Where this peculiar comparison is meant to lead is by no means clear.

Dr. J. G. Bennett (Dec. 20, 1947, p. 1012) says that mothers nowadays "are unable to suckle their own progeny for more than a week or two" owing to underfeeding. If he means *some* mothers, then his statement has probably always been true. At the moment something like 40% of mothers in this part of the country completely breast-feed their babies, and I know of no evidence that this is a worse performance than obtained, say, three or ten years ago. There is no doubt, also, that many of the lactation failures are due to causes other than undernutrition. If Dr. Bennett means *all* mothers in his practice, or if he believes that there has been an appreciable deterioration in recent years, then it is most important that he should report his facts carefully and temperately, in accordance with scientific usage.

I have been at pains to search for factual reports of diets actually consumed during the past few years. The number of published diet surveys can be counted on the fingers of one hand. I know the Ministry of Food carries out surveys routinely, but its reports are not published, and hence official figures cannot be judged in their full context. Why the secrecy? On the clinical side, there is a similar scarcity of published research, except in respect of school-children. Whether or not the country has recently become seriously undernourished, there is certainly a great need for facts, publicly presented in a scientific manner. Does the M.R.C. not think so? One wonders what facts the new B.M.A. Nutrition Committee is going to deal with.

It may not be entirely incorrect to suppose that much of the publicity given to many wild and unsupported opinions of certain medical men and politicians is based on a sincere belief that the present Government is pursuing a misguided policy. Governments, after all, are fair game for critics. But surely the best medical policy would be to deal in facts which speak for themselves, and not to parade half-truths disguised as learning, or violent opinion in the guise of authority? Although medicine is not altogether an exact science, we are generally credited with being a scientific profession, and I am optimistic enough to believe that the scientific method pays, even in politics.—I am, etc.,

Foresterhill, Aberdeen.

ANGUS M. THOMSON.

Streptomycin and Tuberculous Meningitis

SIR,—It was interesting to read in the *Journal* of Dec. 6, 1947 (p. 897), the account of streptomycin in the treatment of tuberculous meningitis in children by physicians of the Hôpital des Enfants in Paris. Their experiences in technique and dosages will no doubt be of the greatest value to many who are now entrusted with the care of patients suffering from what has been one of the most fatal forms of tuberculous disease. It has recently been my good fortune to observe a series of over 100 cases of tuberculous meningitis and miliary tuberculosis treated with streptomycin, dextrose sodium sulphate, and vitamin A in the Hôpital Meyer in Florence by Prof. Cocchi and his associates, and one can confirm the excellent results which have been claimed by these workers. The technique used in Florence and in other centres, however, varies considerably from that described by Debré and his co-workers in Paris. Indeed, technique and dosages have still to be studied in much detail, and before final pronouncement can be made on the

It may be of interest to your readers, therefore, to know that the Interim Commission of the World Health Organization, realizing the importance of the subject, decided at its Fourth Session in Geneva in August, 1947, to call a meeting of a number of international experts who have had practical experience in the use of streptomycin with a view to correlating results so far obtained and, if possible, to make available the most recent data concerning methods of treatment. Evidence from a number of countries points to the need for such guidance as may be forthcoming from such a group of experts. It is anticipated that the Expert Committee of the World Health Organization Interim Commission, which meets in Geneva in February, 1948, will be able to complete the arrangements for this conference so that it may be held not later than April, 1948.—I am, etc.,

World Health Organization.

J. B. McDONALD.

Diet and Peptic Ulcer

SIR,—Alkalis and atropine relieve symptoms, but ulcer is a deficiency disease. This is indicated by its historical rise, and by its class distribution up to the war, when rationing put us all on a more just level. Ask any senior surgeon how many "perfs." he used to deal with in his West End practice. Experimentally it was proved long ago by McCarrison's rats, fed on Travancore coolie diet; the findings of Sommerville and others in India are in support; also the recent work of Illingworth in Glasgow, when the incidence in slump-fed workers rose to a peak as soon as war work imposed its added strain. Of course there are other factors, notably strain: we are dealing with men and women, not test-tubes.

Clinically, anyone may convince himself (and cut down his waiting-list) by forgetting all he once learnt about "bland" diet, which means unsupported starch for most people, and feeding his ulcer cases on milk (no matter what anybody says) and a robust whole-cereal diet. If his courage fails him, he should remember that hibernating animals swallow a chunk of wood or something similar to keep the stomach in good tone during the winter fast. In default of a reliable whole-meal bread, and especially in parts where oatmeal porridge is not popular, some preparation of whole wheat germ gives rapid results in healing and freedom from relapse. The coincident spasticity of the colon also disappears. Only the long-standing indurated cases should come to the operating table.—I am, etc.,

Edinburgh.

A. G. BADENOCH.

Antral Infection in Children

SIR,—Mr. F. M. Walker (Dec. 6, 1947, p. 908) draws attention to the frequency of antral infection in children with unhealthy tonsils and adenoids. He states that a considerable proportion of the cases which were referred for tonsillectomy had failed to benefit thereby. 1,779 children, from a child population of 70,000, were operated upon by him during the year 1946.

The school population of Cornwall is about 36,000, and in 1946 about 325 operations for removal of tonsils and adenoids were carried out under the county council scheme, of which number we were responsible for 226. We find that the parents of these children are nearly always delighted with their improvement following operation. All the children are seen by one of us on at least one occasion, in the presence of a parent, before operative treatment is advised. They are seen again three months after operation. In many instances their tonsils and adenoids are not removed until the child has been under observation at out-patient clinics for six to twelve months.

The absolute indications for operation are considered to be: (1) Recurring attacks of tonsillitis; (2) persistent enlargement of the tonsils and adenoids sufficient to cause mechanical obstruction. Among resulting symptoms are snoring, difficulty in eating, repeated attacks of earache or deafness, and inability to throw off head colds.

Children are often referred for advice because they catch frequent colds, which, on questioning, are found to clear in a few days. Others are referred because they have nasal obstruction or catarrh which is found to be due to chronic sinusitis or rhinitis, often with a history of allergy or a deflected nasal septum. Removal of these children's tonsils and adenoids will of course lead to disappointment. We also find signs of antral

infection in a number of children selected for operation. As Mr. Walker suggests in his final comments, this resolves in the vast majority of cases after removal of the diseased tonsils and adenoids. He considers that the unsatisfactory results following tonsillectomy and adenoidectomy are due to sinusitis; we consider that they are more likely to be due to an incorrect selection of children for operation.—We are, etc..

Turo, Cornwall.

T. M. BANHAM.

Residual Prostatitis

SIR,—We have read with great interest Dr. F. C. Bourgault Du Coudray's excellent article on residual prostatitis (Oct. 25, 1947, p. 651). Such a condition has been observed by us in a large number of cases, and assuredly also by many others, after sulphonamide or penicillin treatment of the urethral-process gonorrhoea. Some cases were treated for months and even years with massage, diathermy, and high supplementary doses of antibiotics notwithstanding the fact that repeated cultures of prostatic fluid and of semen were sterile or showed some diptheroids or Gram-positive cocci or bacilli. Streptomycin was used without success in 2 cases.

The persistence of pus cells in the prostatic fluid indicated the existence of an infection whose true nature we have cleared up in quite a few cases after dark-field observation of the prostatic fluid. In a recent communication to the III Pan-American Congress of Urology (Rio de Janeiro, Sept. 14-20, 1947) we referred to 50 cases of such a type of prostatitis observed in V.D. clinic patients: in 6 (12%) we found spirilla, some morphologically similar to *Sp. dentium*. Latterly we have found in 7 other cases spirilla, in 3 *Tr. vaginalis*, and in 2 an association of both these micro-organisms. All cases were cured rapidly, with arsenical therapy—trivalent, pentavalent, or arsenoxide.

In 3 out of 10 cases in which we did not find spirochaetes or protozoa we obtained rapid and remarkable results with the arsenical therapy, based on the knowledge that the former micro-organisms may disappear, breaking up into coccoid or granular forms (Dutton, Leishman, Balfour, Nicolle, Coutts, Marchoux, Chorine, etc.).

As regards the negative action of penicillin in cases where spirochaetes have been found, it is of convenience to remark that this drug does not act equally on the different types and that even *Sp. pallida* sometimes requires very large doses in order to be destroyed.

When prostatic fluid contains numerous pus cells we dilute it with tepid normal saline and examine a drop of the dilution. An excess of pus cells impedes the free movements of spirochaetes and of the cilia of trichomonads, rendering their search almost impossible. Following this practice we have frequently been able to demonstrate the presence of these micro-organisms in fluids that had been declared sterile.—We are, etc..

Cheaper Heparin

SIR,—Recent correspondence on heparin and dicoumarol prompts me to write on the subject of these anticoagulant drugs. Whatever may be the views held by physicians on the value of anticoagulants in the treatment of coronary thrombosis, surgeons should be in no doubt about the value of anticoagulant therapy, properly managed, in cases of post-operative venous thrombosis and embolism. In view of this fact, it is perhaps surprising that these drugs are not more widely used.

There would seem to be two reasons for the present state of affairs: on the one hand we have heparin, a highly effective, safe, and expensive drug, while on the other hand there is dicoumarol, a cheap, potentially dangerous, but more readily obtainable drug. Experience with dicoumarol seems to vary greatly, and, although one knows some who have used it without experiencing any trouble, there are many who report serious and even fatal complications following its use. While it is clear that the most careful laboratory control is essential in dicoumarol therapy, it is doubtful whether a substance which has been described by no less an authority than Jorpes as exerting "a kind of toxic narcosis of the liver cells, the depth of which it is difficult to control," is really the drug of choice in the treatment of thrombosis.

At the present time an average day's treatment with heparin costs more than five pounds, whereas that with dicoumarol may cost less than a shilling. Under these circumstances it is hardly surprising that dicoumarol is sometimes tried (often, it is true, under inadequate laboratory control), found wanting, and discarded, while heparin, being expensive and in short supply, is used far too little.

Since the great value of heparin should need no emphasis I would like, through your columns, to put in a strong plea for the manufacture of a plentiful, cheap, and reliable brand of heparin. Doubtless other readers will be ready to express their views and, if necessary, to encourage the commercial drug firms to satisfy our needs.—I am, etc..

REGINALD S. MURLEY.

Drug Addiction

SIR,—I was interested in your annotation on drug addiction (Dec. 13, 1947, p. 965). The group of opium eaters who appear to be in an "arrested development" stage of addiction must be familiar to medical officers who served with Indian troops in the recent war. It was found that Indian troops, who were able to obtain supplies of opium in India quite easily, presented a problem when posted out of India to countries where opium was not so readily obtainable. At first opium eaters were posted back to India, but later policy was changed, and these men were supplied with a limited amount of crude opium up to a maximum of 300 gr. (20 g.) per month.

In my unit half a dozen men were kept efficient and healthy with such a maintenance dose. Some received 200 gr. (13 g.), the others the full 300 gr. monthly. I followed these men over a period of 2½ years and found that their work was satisfactory in every way; they did not make frequent appearances at sick parade nor did they seek increasing doses of opium to remain in such equilibrium. I made attempts to break them of the habit, but since they were men over 30 with a history of ten years or more of taking the drug success was neither anticipated nor achieved.

On the other hand, a dozen or more young soldiers posted to the unit direct from India were broken of the habit quite easily by immediate withdrawal of the drug. This group suffered virtually no withdrawal symptoms and emphasizes the point brought out by your annotation—that it is a mistake to apply the term "drug addiction" to all cases in which drugs are taken merely to produce euphoria.—I am etc..

Bristol

PHILIP JACOBS.

Child-bearing and Tuberculosis

SIR,—Dr. C. J. Stewart and Dr. F. A. H. Simmonds (Nov. 8, 1947, p. 726) have noted that the majority of physicians who have recent experience in the matter agree that pregnancy does not activate tuberculous disease; they have confirmed this themselves by a statistical analysis of a large series of patients, and they have drawn the conclusion that abortion is not a therapeutic agent in tuberculosis. Their comment in your issue of Dec. 27, 1947 (p. 1056), that effective advice concerning birth control had not been given to the patients in their series, and their suggestion that such advice is advisable especially for two years after the disease has become quiescent, is less logical, because they have already shown that in spite of lack of such advice, and also the lack of therapeutic abortion, the patients with active disease in their series who were pregnant compared not unfavourably in results with a control group with active disease who were not pregnant. Dr. R. C. Cohen found in his analysis of the Black Notley cases that a woman who became pregnant soon after quiescence of the disease would as likely do well as a woman who became pregnant later.

Admittedly, unlimited pregnancies should not be encouraged in tuberculous women. But the psychosomatic background of tuberculous disease is becoming increasingly perceptible. Conjugal felicity is important for a tuberculous woman, as for others, and if by effective birth control is meant artificial contraception it is interesting to speculate whether our generation, to whom advice in artificial contraception has not been wanting, is the more blessed in happy marriages. Might it not rather be better for the tuberculous woman and her husband to avoid a facile solution and by mutual co-operation and sacrifice to grow in that mutual respect on which happy marriages are built?

Another point is that I have followed up a number of patients who have suffered from non-pulmonary tuberculosis and who later married, and have found that pregnancies were unusual among them. This difference between patients with phthisis and patients with other forms of tuberculosis offers an interesting commentary on the pathogenesis of the disease.—I am, etc.,

Black Notley, Essex.

M. C. WILKINSON.

A Method of Abdominal Palpation

SIR.—The method of abdominal palpation described by Dr. E. W. Price (Nov. 1, 1947, p. 703) is, no doubt, almost the inevitable one when there is no table or chair available and when a number of patients are to be examined. But at a crowded out-patients of an Indian mofussil dispensary, where just a stool and a chair can be improvised, I have found a modification of the method more useful. The patient is seated on a stool on the examiner's right side, facing him and the light. The abdominal palpation is done in the same way as described by Dr. Price, with the patient bending forward. The sitting position of the patient is superior to the standing one for abdominal palpation, as it ensures a more complete relaxation of the abdominal muscles, because the thighs are flexed at right angles to the trunk.—I am, etc.,

Poona City, India.

P. L. DESHMUKH.

Prickly Heat: A Simple Remedy

SIR.—Recent references in the *Journal* to prickly heat (Nov. 15, 1947, p. 779; Dec. 20, 1947, p. 1012) make me wonder once again how many of those who interest themselves in this complaint have tried treating it with perchloride of mercury lotion. If a solution of perchloride of mercury in water, 1 in 500, is dabbed twice daily over the affected area and allowed to dry on the skin, the trouble is finished, in my experience, within two or three days, and further occasional applications prevent its return. This simple treatment was told me many years ago by a colleague in the Colonial Medical Service: I have never seen it mentioned in print, and have never known it fail in practice.—I am, etc.,

Nairobi, Kenya.

C. J. WILSON.

Relief from Pain in Obstetrics

SIR.—May I, as a woman practitioner, support Dr. John Elam's timely plea (Dec. 27, 1947, p. 1055) for the relief of pain in obstetrics? I have just returned from a most heartening visit to a maternity home in the South of England where "trilene" and air, and gas and air, are available and efficiently administered to all women in labour who desire anaesthesia. What impressed me, however, was not the number of women who made use of this opportunity, but the far greater number who enjoyed—literally enjoyed—bearing their babies without any anaesthetic, drug, or hypnosis.

If anaesthesia is the only way whereby the pain in labour can be relieved, by all means let us have adequate facilities for its effective administration. But if the pain of labour can not merely be relieved but virtually prevented by perfectly simple, straightforward physiological methods, why not employ these, rather than in ignorance allow a "normal" labour to progress in such a manner that anaesthesia, with its accompanying dangers (however small), becomes necessary?

Having read G. Dick Read's *Revelation of Childbirth*, and taken the opportunity of verifying with my own eyes the practical results of the application of his theories, I am convinced beyond any shadow of doubt that the answer to the 'scandal of the 'woman in pain' lies, not in the reduction of pain "to a minimum" by anaesthesia, as Dr. Elam unambiguously suggests, but in its prevention by education. That such a revolution in the conduct of labour is possible there can be no doubt in the minds of those of us who have been privileged to experience over and over again the peacefulness of a really normal labour, and witness the healthy joy of a mother when, after such a labour, she reaps her reward in full consciousness of her achievement.

Doctors and midwives in many parts of the country to-day are practising, or learning to practise, the methods whereby such results are made possible. But until the principles and

practice of Dr. Dick Read's great work become part of the curriculum in all medical schools and midwifery training centres instead of, as at present, in an isolated and enlightened few, there will be many who, with me, deplore the grave and tragic injustice that is now being done to the mothers of this country and to humanity in general. For what is callousness, or indifference, to extreme suffering but a natural protective reaction towards the acceptance of its inevitability?—I am, etc.,

York.

MAILO J. ELLIS

Asthma and the Inhaler

SIR.—Dr. James Kay (Dec. 20, 1947, p. 1011) describes the effectiveness of an inhaler in relieving an attack of bronchial asthma. It is true that the method is simple to use and rapid in its effect, and this makes it particularly important that the contraindications to its employment should be recognized. The fluids employed in asthma inhalers usually consist of solutions of vasoconstrictor and antispasmodic drugs such as adrenaline, pituitary extracts, atropine, and papaverine, and the effect of these vaporized solutions on the congested bronchial mucous membrane is to produce a rapid vasoconstriction and paralysis of the cilia. The asthma is relieved by the shrinking of the previously swollen bronchial mucosa, and provided the inhalation is not repeated day after day no harm results. But if an inhaler is used several times daily for weeks or perhaps months at a time the cilia of the bronchial tree become destroyed and the bronchial mucosa becomes thickened. The result of this is that expectoration becomes more difficult, shortness of breath on exertion more pronounced, and the attacks of dyspnoea recur more frequently. These symptoms do not occur as a result of repeated adrenaline injections.

In general the higher the adrenaline concentration in the inhalant solution the more rapid is the relief obtained and the quicker is the bronchial mucosa damaged. There is also a risk of adrenaline poisoning when a strength of 1 in 100 is repeatedly inhaled (*Journal*, 1946, 1, 671), and I reported such a case (*Journal*, 1946, 1, 864). Ephedrine is less harmful as an inhalant than is adrenaline, and the suggested prescription of 1% cocaine and 1% ephedrine in 4% glucose saline (*Journal*, 1946, 1, 671) is preferable to the inhalant solutions usually employed.

It may sometimes be necessary to prescribe an inhaler for patients whose attacks are so severe that relief is not obtained by the usual oral remedies, and when, in addition, adrenaline injections are not practicable; but these patients must be warned of the risks of continued use.

Rhinologists know that spraying the nose with adrenaline produces rapid temporary relief to nasal obstruction by shrinking the nasal mucosa, and that this relief is followed by increasing obstruction. No rhinologist therefore would prescribe an adrenaline nasal spray for constant use. The employment of an inhaler is equally undesirable in chronic asthma.—I am, etc.,

London, W.1.

CLEMENT FRANCIS.

Foreign Body in the Vagina

SIR.—Apropos the letter from Dr. G. J. Grainger (Dec. 20, 1947, p. 1011) I can quote a case which I think is worthy of a place alongside the one he describes. I had been attending an old lady of over 80 for a considerable time, when, in November, 1942, she began to complain of a feeling that her insides were falling out. When I came to examine her I found that the perineum simply did not exist. On making a vaginal examination my finger encountered a foreign body which on withdrawal proved to be a dried-up twisted old ring pessary. There were no ulceration and no bleeding. On going into the history more thoroughly the patient was very vague but maintained against all attempts to dissuade her that the ring must have been *in situ* for 41 years.

Perhaps the most interesting feature of this case lies in the subsequent history. I continued to see her at regular monthly intervals. Her only complaint was of dizziness due to a raised blood pressure. In February, 1946, she began to complain of abdominal discomfort accompanied by attacks of diarrhoea. On examination I found her belly to be distended. A rectal examination revealed a hard mass invading the lumen of the

'VIBELAN'

Vitamin B Compound B.D.H.

'Vibelan' contains the principal members of the B group in the balanced proportions which have been found necessary for effective utilisation of proteins and fats and, more especially, carbohydrates. It is thus of particular value in those cases of debility and lassitude with which medical men are so frequently confronted today. Each tablet contains vitamin B₁ 0.5 mg., riboflavine 0.75 mg., nicotinamide 7.5 mg., in a yeast extract base. Four tablets provide the normal daily requirement of these vitamins.

Further details are available on request.

Vitamin Therapy - its uses and limitations

BRIDGING THE GAP

More care, skill and knowledge than ever before are required in the buying and preparation of food if all nutritional requirements are to be fully met by available supplies.

During this winter we may expect to see patients who, through lack of knowledge or shortage of time, have failed to maintain their normal standard of nutrition.

For many, the greatest help that can be given is the provision of a supplement which will balance the average gap between supply and requirement.

Such a supplement, designed especially for this purpose, is

COMPLEVITE A single supplement for multiple deficiencies

The recommended adult daily dose provides:—

vitamin A	2,000 i.u.	vitamin C	20 mg.	iodine	not less than 10 p.p.m. c.i.b.
vitamin D	300 i.u.	calcium	160 mg.	manganese	
vitamin B	0.6 mg.	iron	18 mg.	copper

rectum about 3 in. (7.6 cm.) from the anal orifice. This was producing almost complete obstruction. Operation was firmly refused and she died on March 17, 1946. It is tempting to relate the final condition to the ring episode. Unfortunately no post-mortem examination was allowed, so no pathological evidence exists. Certainly I had at the time no doubt that clinically the growth was a carcinoma.—I am, etc.,

Bridlington, Yorks.

C. J. GORDON TAYLOR.

SIR.—I was interested to read (Dec. 20, 1947, p. 1011) about Dr. G. J. Grainger's finding a bone nozzle in the vagina. While I agree that it was remarkable that it should be impacted in the pessary, I do not feel that it should be expected to cause any more symptoms than the pessary itself. Surely this is a case of straining at the enema and swallowing the pessary. Perhaps if it were given the chance the patient's cat would oblige by swallowing them both.—I am, etc.,

London, S.W.12.

W. P. M. DAVIDSON.

The Lazy Eye

SIR.—Your recent correspondence on "The Lazy Eye" has drawn attention to the significant number of adults who have subnormal visual acuity in one eye. The figures quoted by Dr. G. C. Dansey-Browning (Nov. 15, p. 796) and Dr. Alan Watson (Dec. 6, p. 933) emphasize the seriousness of the problem. Mr. T. Keith Lyle (Sept. 6, p. 398) stressed the need for treatment at an early age, and surely this is the pointer to the root of the trouble.

The present school ophthalmic service is essentially curative, and until it becomes preventive the incidence of visual defects at school-leaving age will continue to rise. A school child does not receive any ophthalmic treatment until the error becomes manifest to teacher or parent, or a drop in acuity is revealed by a medical examination. The Board of Education's 1931 report "On Problems Connected with Defective Vision in School Children" recognized the need for treatment of ocular defects at the earliest possible moment, before faulty visual habits become established in the children. The committee stated that a regular objective ophthalmic examination of every child was desirable in order that visual defects should receive early treatment, but it doubted if financial and administrative difficulties would permit. Now in 1947, sixteen years later, the position is not changed, and it is obvious that until yearly ophthalmic inspection of every school child is begun, coupled with adequate provision for the visual care of pre-school infants, the number of adults with "lazy eye" and other ocular troubles will continue to increase.—I am, etc.,

Henley-on-Thames.

S. BLACK.

Sterilization of Syringes

SIR.—The important question of sterilization of syringes, needles, and specula has been discussed recently in your columns, and we should like to make the following comments on the advice given. You state in "Any Questions?" (Oct. 25, 1947, p. 680) that, in the absence of an autoclave, the best method for sterilizing the above articles is to place them in a dry oven at 150° C. for one hour. This time is inadequate. The Medical Research Council War Memorandum No. 15 states: "Syringes and needles are placed in the oven while it is cold; the time of sterilization is not less than one hour after 160° C. has been reached. The oven should be allowed to cool before the syringes and needles are removed." The M.R.C. Memorandum also advises reliable thermostat and temperature control and control tests with infected material containing spores. These latter precautions are important because when, as is usual, syringes are sterilized in wrapped or plugged test tubes, there is a considerable time lag before the whole of the syringe is actually at the temperature of the oven, and this time lag must be allowed for in the time required for sterilization.

There is a comment by Messrs. John Foster and C. H. le May (Nov. 22, 1947, p. 854) on this question of hot-air sterilization. They quote Hanne¹ in support of their contention that sterilization by means of hot air is an unsatisfactory process. In fact, what Hanne's work emphasizes is the inefficiency of most of the hot-air sterilizing ovens which he tested and the inadequacy

of the so-called "sterilization" techniques which were being employed. Hanne's failure to kill *B. mesentericus* under the conditions of his experiments should not be quoted as a condemnation of hot-air sterilization in general. His work does, however, call attention to the necessity of ensuring that the temperature shown by the oven thermometer is being maintained equally throughout the oven.

Although many ovens fall short of this ideal, there is one made by a reputable British firm which is stated to have a maximum temperature variation throughout the oven of $\pm 1^\circ \text{C}$. The question of hot-air sterilization was discussed very fully in a letter on "The Sterilization of Sulphonamides" which appeared in the *Lancet* (Sept. 12, 1942) from Prof. Long of the Johns Hopkins University School of Medicine. To quote from this letter:

"We obtained the most heat-resistant spore-formers we could find—one strain of *Cl. novyi* which the suture manufacturers use as a control organism and a strain of *Cl. sporogenes* used by the canners as a control organism. Most of the information in textbooks concerning the heat resistance of spores in hot-air ovens was built up before the present accurate thermo-electric instruments were available. Since the temperature usually given for hot-air sterilization (160° C. for one hour) is so near the melting point of sulphanilamide (163° C.), we decided to restudy the resistance of some of the spores, making use of some of the more modern instruments with extended time as is practised by some canners. It has been found that the most resistant spores of *Cl. novyi* and *Cl. sporogenes* can be killed at a temperature far below the melting point of sulphanilamide if the time element is extended sufficiently: 130° C. kills these organisms in four hours but not in three; 140° C. kills in three hours but not in two; 150° C. kills in two hours. Various types of forced air ovens have been tried, both electric and gas. The above temperatures will not hold for static ovens or ovens improperly baffled so that one obtains cold spots.

Further suggestions on the sterilization technique for the preparation and administration of solutions for intra-spinal anaesthesia are given in a memorandum published recently by the Public Health Laboratory Service and the London Sector Pathologists Committee (*Pharmaceutical Journal*, 1947, 159, 428).

We think that it must be agreed that sterilization by dry heat is a satisfactory method provided that the following requirements are met: (1) An adequate temperature must be maintained for an adequate time. (2) The time of sterilization must begin from the time when the whole article is at the desired temperature. (3) The oven employed must not have "hot" or "cold" spots. (4) Attention must be given to the circulation of the air in the oven if big batches of items are being sterilized. (5) A careful check must be kept by means of thermostat thermometers, and contaminated controls to ensure that the process is efficient. The controls should be spaced throughout the batches.—We are, etc.,

Hertford.

Space for X-ray Departments

SIR.—I am much obliged to Dr. Douglas Gordon (Dec. 1, 1947, p. 977) for drawing my attention to the recommendation of the British X-ray and Radium Protection Committee. The plan which I put forward, as Dr. Gordon agrees, was stated not attempt perfection in detail, and there is therefore no need defend it. It is hoped, however, that the interest this plan may arouse may be on general principles rather than concerned with detail. Nevertheless, it is obviously important that attention should be drawn to these regulations, which were not only unknown to me but also to a distinguished architect. As I. Gordon has pointed out, even architects of the Ministry of Health are unaware of these regulations, and this emphasizes the need for some co-ordination and specialization in the designing of hospitals.

Many hospitals have been built by excellent architects who have been equally at home in designing a hospital, a house, hotel, a cinema, a school, or a town hall. Recently the need for some specialist in hospital construction has been brought to my attention in my efforts to improve the lighting,

operating theatres. The amount of contradictory advice I have received from persons of no experience is quite amazing, and I am now trying to find someone who can really give valuable advice on this most important subject.

In this age of planning one hesitates to suggest a further group of planners, but at present in hospital construction the blind are leading the blind, and much time, energy, and money is expended in attempting to remedy the consequences of faults of design that ought never to have occurred. It would appear to me that either the Ministry of Health or the British Institute of Architects should consider this matter with a view to seeing that recommendations of special bodies should not pass into oblivion, and that expert advice on the special problems of hospital construction may be readily available.

Many of our hospitals are now quite out of date, badly sited, and in a poor state of repair. It is obvious that as soon as circumstances permit a great building of hospitals must take place, both to replace worn-out and obsolete buildings, and to provide new beds so urgently needed both for present and future needs. It was with a view to suggesting the general principle of self-contained units as the basis of hospital construction that I submitted my article (*Journal*, Nov. 22, 1947, p. 832). The scheme is still embryonic, and therefore any criticism that may beneficially influence its development is most welcome.—I am, etc.,

Hove, Sussex.

H. J. McCURRICH.

B.C.G. Vaccination

SIR,—May I remind those of my fellow-countrymen who "still linger shivering on the brink and fear to launch away" that in December, 1947, the Norwegian *Storting*, inspired by the Norwegian health authorities, passed a law for compulsory vaccination against tuberculosis? The easy passage of this law through the national legislature was assured by the same public health authorities, whose mustering of the evidence in favour of so radical a step was masterly. May I now suggest that we act on John Hunter's famous advice to Jenner in this way that, instead of weaving out of second-hand material gossamer threads of speculative agnosticism, we visit, in no tip-and-run spirit, the Scandinavian B.C.G. centres and there seriously study the mass of evidence accumulated over a score of years and still in large part not yet published? Quite possibly we might thus retrieve part of the march the Scandinavians have stolen on us. Might not this be a wiser course than to assume that their observations and conclusions are all wrong, and that we must make a fresh start in England on truly intelligent and impenetrable lines?—I am, etc.,

Sunnfjord Norway

CLAUDE LILLINGSTON.

Future of Almoners

SIR,—May I try, however belatedly, to comment on the points raised by Dr. Trevor H. Howell's letter on "The Future of Almoners" (Nov. 22, p. 843)? His contention that almoners spend most, though certainly not all, of their time and energy in caring for patients suffering from short-term acute illness to the detriment of those generally termed the chronic sick is undoubtedly true. There are obvious reasons for this, such as the small number of almoners in most hospitals, which necessitates a limitation of cases dealt with, and the fact that the primary duty of almoners, as an ancillary service to medicine, is to carry out the requirements of the medical staff, which as a rule centre on constructive work for those cases where conditions of home and employment directly affect health.

None the less, few almoners would claim anything but profound dissatisfaction at the present situation. Probably the reason for any apparent lack of interest in these long-term cases is not, as Dr. Trevor Howell suggests, their absorption in administrative and financial duties, but rather a profound feeling of helplessness in the face of a problem so vast that it can only be tackled successfully by a campaign in which the medical and nursing professions, public authorities, social workers, and the community at large all play their part. At present there is a neglect of the chronic cases, and for those who seek their hospitality there is a dearth of rehabilitation. Small nursing-homes run for the chronic are extremely unsatisfactory in every way, while the

chronic wards of municipal and county hospitals, housed in many cases in buildings of prison-like grimness, are as a rule overcrowded and understaffed to a deplorable degree.

The long-term case, while awaiting admission to such wards, either remains at home with no nursing at all or else in a general hospital blocks the beds needed for acute cases. If and when they are admitted to these chronic wards they find only too often that in entering they give up all hope of any life which can be called life. There is no feeling of hopefulness, no encouragement to improve, no remedial treatment, no occupational therapy, and, moreover, no selection of cases, with the consequence that the young person with possibly many years to live lies cheek by jowl with the old and senile. If by a miracle they improve sufficiently to be discharged, there is no halfway house to which they can be moved where they can stay long enough to be fitted even for a moderately normal life.

Much-needed interest is now being shown for old people, and admirable plans are being made for them in the future, but one wonders who will raise the standard of care for the younger chronic and for the middle-aged person who is slipping into chronic illness just because of lack of the right accommodation and the right treatment. I would like to assure Dr. Trevor Howell that if any constructive plans can be made he will find almoners as a whole not only ready but eager to play their part.—I am, etc.,

London, W.C.1.

C. MORRIS.

Road Accidents

SIR,—In my comment (Nov. 22, p. 843) on Dr. Kenneth Soddy's paper (Oct. 18, p. 623) I conceded the importance of the psychological aspects of accidents but stressed the need for some short-term action. I suggested low speed and strict law enforcement. If Dr. Soddy does not agree, what is his short-term solution while research is going forward? May I remind him that in the latest month for which we have figures another 500 persons have been killed and 14,000 injured on the roads?

If Dr. Soddy considers our solution to be remote from reality, I would point out that its success has already been demonstrated in Providence, U.S.A. In that city, following a black period of accidents, a limit of 25 m.p.h. was introduced in 1938 and strictly enforced. Since then Providence has been the most accident-free city in the U.S.A.

In his research into the psychological causes of accidents perhaps Dr. Soddy will look into the effect on the mentality of many drivers of the propaganda that "speed is not the cause of accidents" and that motorists are "persecuted." Have not those who indulge in such propaganda in the face of the continued slaughter forgotten the debt which they owe to common humanity?—I am, etc.,

T. C. FOLEY.
Secretary.

The Pedestrians' Association.

British Medical Students' Association

SIR,—Much has been said of late in your columns (Dec. 1, 1947, p. 931, and Dec. 20, p. 1008) and elsewhere concerning the political colour of the British Medical Students' Association. At the last Executive Committee meeting of the Association on Dec. 20, 1947, this question was brought up by the secretary of the London Region. It was decided after discussion to publicize the following points:

(1) The Association does not concern itself with political activities. We do co-operate with the B.M.A. on such matters as curriculum reform, medical films, status of medical students and newly qualified practitioners, etc., and with the International Union of Students on the organization of the Student International Clinical Congress, to be held by us in July, 1948, but at the same time are in no way influenced by their policies.

(2) The files and correspondence of the Association are at all times open to inspection by students and qualified members of the profession at B.M.A. House, W.C.1, and copies of our Annual General Reports and Constitution will be sent to any interested party on application.

In conclusion, Sir, may I thank you for the use of your columns.—I am, etc.,

S. M. DRANZ.
President, B.M.S.A.

A Peck of Troubles

Messrs. J. FISHER and R. A. HINDE write: The British Trust for Ornithology is inquiring into the opening of milk bottles by tits and other species of birds. This habit is not universal and may have spread in an orderly way through the tit populations. If so, problems of the greatest interest to students of animal behaviour are involved. In reaching the closing stages of our inquiry, we have reviewed the collected information and are anxious to consult a group of educated observers distributed evenly over the country. Such a group is formed by the medical practitioners of Great Britain. While we fully realize how very busy your readers must be, we would be extremely grateful for postcards, addressed to R. A. Hinde, 31, Mount Pleasant, Norwich, giving the following information: (1) Species of birds; (2) civil parish or county; (3) year in which observer could first have noted the habit (i.e., year since which observer has lived in the district); (4) year since which milk has been available in bottles to tits in the district; (5) year in which opening of milk bottles was first actually observed; (6) type of bottle closer; (7) any other information, method of opening, etc.; (8) name and address of observer.

A Method of Abdominal Palpation

MEDICUS writes: The method described by Dr. E. W. Price (Nov. 1, 1947, p. 703) is not a new one. It can be found in the 3rd edition (1947) of the textbook on *Percussion, Auscultation, and Palpation* by L. Dunner and R. Neumann. The book, written in German, is, it is true, not easily obtainable in this country. I have been using the method for many years and was always very satisfied with the results.

Fluted Vials

Dr. E. SUTHERLAND-RAWLINGS (London, W.2) writes: Frequently there have occurred tragedies from the inadvertent use of poisonous solutions which have been mistaken for therapeutic substances of a less dangerous nature. These mistakes arise chiefly on account of: (1) Ampoules or rubber-capped vials of same manufacture which bear no distinguishable marking whereby the busy practitioner's attention can be drawn immediately to the knowledge that he is using a dangerous drug. (2) In some cases the print is small and liable to become indecipherable through damp, age, or wear. . . . To obviate this I would suggest that all vials and ampoules containing dangerous solutions or tablets be grooved or fluted on the outside so that they are immediately distinguishable to the touch, and that the glass be appropriately marked in vivid colour to arrest the attention. If such a recommendation could be enforced under the D.D.A., I feel sure further tragedies of this kind would be averted.

Penile Carcinoma

Dr. I. GOTTLIEB (Sheffield) writes: With all due respect to Mr. W. Sampson Handley, I wish to point out a gross inaccuracy in his letter (Dec. 20, 1947, p. 1010). Zipporah, who circumcised her son (Exodus iv. 25), was the wife of Moses (Exodus ii. 21) and not the wife of Abraham, though her father, Jethro, was a Midianite and thus a descendant of Keturah, second wife of Abraham (Genesis xxv. 1). Therefore Zipporah could obviously not have taught Abraham the rite of circumcision. Abraham and Ishmael were the first people in the Bible to be circumcised (Genesis xvii. 26), and the Midianites, being descended from Abraham, must also have practised circumcision. My reason for writing is that I cannot allow such a misconception to appear in print above a name as distinguished as that of Mr. W. Sampson Handley.

Early Inoculation

Dr. ROMANA G. BARTELOT (Tisbury, Bath) writes: I found the following extract when turning out my father's old deeds and manuscripts and family papers. Thomas Bartlett, of Holwell, Dorset, was a direct ancestor, and his diaries extend from 1735 to 1750. In the diary for 1743 is this entry, "Memorandum the 17th of January this year, my son and Miss Molly Tregonwell were both inoculated by Mr. Goldwyer, Surgeon of Blandford, whose pay for the said inoculation was 20 guineas." (This when a year's schooling was only 15 guineas and one gallon of brandy 7s.) "The aforesaid operation was performed on Monday, the aforesaid 17th of January, about 3 o'clock in the afternoon at Holwell. The smallpox came out on my son the ninth and tenth days after he was inoculated, but on Miss Molly not until the eleventh and twelfth days after. They both bred it very easy and had it very light and but a five days sore. My son's arms threw off the discharge and got well where they were inoculated in about 3 weeks after the smallpox was turned, but Miss Molly's arms continued the discharge for six weeks."

* Lady Mary Wortley Montagu introduced inoculation against smallpox into England in 1717.—Ed., B.M.J.

T. W. LIPSCOMB, M.B., M.Ch., F.R.A.C.S.

We announce with regret the death on Nov. 19, 1947, at the age of 72, of Dr. Thomas Walter Lipscomb, chairman of the Australasian Medical Publishing Company, Limited, and former president of the New South Wales Branch Council of the B.M.A.

Thomas Walter Lipscomb was born in 1875, the son of William Griffin Lipscomb, of Maitland, New South Wales, Australia. He qualified M.B., M.Ch. at Sydney, and went into general practice at Leichhardt in Sydney in 1902. He was a foundation Fellow of the Royal Australasian College of Surgeons. Lipscomb's interests were largely surgical, and in 1903 he was appointed to the surgical staff of Lewisham Hospital, Sydney, where he was for many years the senior surgeon. In 1920 he retired from general practice and gave up his time entirely to consultant surgical work. Lipscomb was a man who took a warm interest in all professional matters and gave sterling service to the many causes he had at heart. He was a member of the New South Wales Branch Council from 1913 to 1931, and its President in 1922-3. He took a prominent part in 1913 in negotiations with the friendly societies of New South Wales, and represented the New South Wales Branch at the Annual Representative Meetings. He was one of the joint honorary secretaries of the third session of the Australasian Medical Congress (B.M.A.) held in Sydney in 1929. Lipscomb took a leading part in the organization of postgraduate education and was chairman of the New South Wales Post-Graduate Committee in Medicine from 1939 to 1944; for many years he was a member of the Board of the Prince Henry Hospital while it was functioning as a post-graduate teaching hospital; he was also a member of the Federal Council of the B.M.A. in Australia.

For over 25 years Lipscomb was closely associated with the Australasian Medical Publishing Company, responsible among many other things for the publication of the *Medical Journal of Australia*. He was also chairman of the Board of Directors of *The Maitland Mercury*, a daily paper owned by his family. Lipscomb was rightly very proud of the activities of the Australasian Medical Publishing Company, which has always maintained the highest standard. He was a man of the greatest probity and always spoke his mind simply and clearly yet without aggression. As recently as September last year he was present at the meeting of the World Medical Association in Paris. Lipscomb had a warm affection for England, and he will be missed by the many friends he had here. Of his family of seven, three sons qualified in medicine at the University of Sydney, and two of them are now practising in England.

HERBERT THOMAS HERRING died at his home in Harley Street on Nov. 22. Educated at University College Hospital, he took the M.B., B.S. Durham in 1887, and the M.R.C.S. in the same year. He acted for many years as assistant to Sir Henry Thompson, who was not only the leading genito-urinary surgeon of his day but also a fervent advocate of cremation and founder in 1874 of the Cremation Society. This work was eagerly taken up by Herring, who was active in the development of the Golders Green Crematorium, founded in 1902, of which he became managing director. At Woking he held the same position, and was for many years honorary secretary of the Cremation Society. Beyond doubt the steady expansion of the practice of cremation was due largely to his incessant propaganda. If in the second half of his life he was mainly a man of one idea, at least it was a sound idea and a progressively successful one. After qualifying, he was house-surgeon at University College Hospital. There, and later, when he joined Sir Henry Thompson, the cystoscope and x rays were unknown. A large part of a urinary surgeon's work consisted in catheterizing sufferers from enlarged prostate and in combating vesical infections due to faulty catheterization by other people—often the patients themselves. Herring devoted a lot of thought to perfecting a technique which should prevent bladder infection, and forty years ago he published his observation

in a volume entitled *The Sterilization of Urethral Instruments*. The aim of his teaching was self-catheterization by patients sufficiently educated to comprehend the meaning of asepsis and the way to avoid cystitis. At that time the day was just dawning when a vast reduction in the number of catheter cases was to take place, so that eventually the usefulness of his technique was diminished. His long career of public service in connexion with the Cremation Society was recognized in 1920 by the award of the O.B.E. Few men have pursued an ideal as steadily as he did for an equally long period.—H. R.

Dr. ARDESHIR HORMASJI MASINA died suddenly after a short illness on Dec. 17, at the age of 36, at the Masina Hospital, Bombay. He was the youngest son of Dr. Hormasji Masina, the well-known Parsi surgeon who had been the founder and principal managing trustee of the Masina Hospital since 1907, the year in which the institution began its life as one of the first voluntary hospitals in India. Ardeshir, like his brothers and his sister, was educated in this country and later entered the medical profession. He went from the Leys School, Cambridge, to Emmanuel College, and completed his training at St. Bartholomew's Hospital. He qualified in 1936, and took his M.B., B.Chir. at Cambridge in 1938. He became house-physician to the medical professorial unit at St. Bartholomew's for a year and later was house-physician to the London Chest Hospital. He also held the post of R.M.O. at Bradford Royal Infirmary. He took the M.R.C.P. in 1940, and proceeded M.D. in 1943, taking bronchiectasis as the subject of his thesis. It had always been his intention to carry on the hospital work which had rested for so many years on the shoulders of his distinguished father. Arriving in Bombay in 1942, he worked there until his death. When his father, who was more than 80 years of age, died in 1946 additional responsibilities fell to him in connexion with the management of the hospital. He became a leading consulting physician, and though his interests were wide he had special experience in diseases of the chest. He brought to Indian medicine a wealth of medical knowledge and culture from the West which combined with his experience of tropical medicine to give him an exceptional breadth of outlook. His scientific attitude to disease would have been of outstanding value to Bombay and the Parsi community in particular. Like his father, who in the earlier years of this century travelled frequently to European centres of surgical culture, and who many times visited this country, Ardeshir had a great respect for and an exceptional grasp of medical progress in Great Britain. Gifted as he was with an acute and alert mind, he was quickly able to grasp the essentials of any problem and to solve it with tact, wise judgment, and precision. Gentle and approachable in manner, he was kindness itself not only to his patients and his colleagues but to those visitors who were fortunate enough to be invited to visit the Masina Hospital. The writer, who was privileged to be his friend since his days at Cambridge, will always remember with gratitude the generous hospitality extended to him during a fortnight's stay at his hospital in 1943. The Masina family always welcomed to their hospital visitors from this country, and their hospitality was genuine and sincere, as only those who know India will understand. By his passing the Masina Hospital has suffered a crippling blow and the medical profession in India has lost one of its outstanding members. We who had the privilege of knowing him will always remember him with sadness and affection, and to his brothers and his sister our deepest sympathy is extended.—P. H. W.

Dr. JAMES FRIDERICK DIGNY WILLOUGHBY died at his home in Southwell on Dec. 17 at the age of 91. Dr. Willoughby was a student at St. George's Hospital, and qualified in 1879. He had lived in Southwell for over 62 years and was in active practice until 1927. In his early days he acted as medical officer to the South Notts Hussars, and during the first world war he was in charge of the V.A.D. hospitals at Burgage Manor and Brackenhurst Hall. For his services in this connexion he was awarded the O.B.E. He had been a J.P. since 1907 and had served on the governing body of the Minster Grammar School for many years. He had always taken the greatest interest in the religious and educational life of the town. He was a member of the British Medical Association for over fifty years, and was chairman of the Nottingham Division in 1926-7. He leaves two sons and one daughter.

Dr. HENRY NATHAN WARNER COLLINS died on Dec. 23, 1947, at St. Dent of University College and King's College, London. He was a student at B.M.S. in 1915 and qualified in 1919, taking the D.M.B. in the following year. He then went on to study at the University of Paris and Lausanne, and in 1927 took the M.D. of Lausanne University. Recently he had been

called to the Bar, and he was well known as a radiologist on the consultant staff of the Weir Hospital and St. James Hospital, Batham; he was consultant physician to the Royal Society of Musicians and to the Children's Rest at Roehampton. He had also been associated with the Chiswick General Hospital and with the Bolingbroke Hospital.

C. A. H. F. writes: By the early decease of Henry N. Warner Collins the Lausanne Medical Graduates' Association loses one of its most distinguished and outstanding members. He was a man of exceptional ability and enterprise. He held many consulting appointments, and his tall and impressive figure will not easily fade from our memories, nor his clear and businesslike script. In his own sphere he will be greatly missed and his place will be difficult to fill. He leaves a widow and one daughter, Cynthia, to whom we extend our sympathy.

A memorial service for Mr. G. F. Stebbing will be held at St. Philip's Church, Kennington, at 12 noon on Monday, Jan. 12.

The Services

In a dispatch submitted to the Secretary of State for War by General Sir Frederick A. Pile, Bt., G.C.B., D.S.O., M.C., General Officer Commanding-in-Chief, Anti-Aircraft Command, and published in a Supplement to the *London Gazette* dated Dec. 18, 1947 Major-General P. H. Mitchiner, C.B., C.B.E., T.D., is mentioned as having given outstanding service.

The relevant paragraph reads: "Major-General P. H. Mitchiner, C.B., C.B.E., T.D., organized the medical services in the Command. He was an administrator of a very high order as well as a first-class medical officer. He rendered great services to the State."

The Efficiency Decoration of the Territorial Army has been conferred upon Lieutenant-Colonel T. C. Williams, R.A.M.C.

DEATHS IN THE SERVICES

The death of Group-Captain HENRY COOPER came as a shock to many friends in the Services and in civilian circles. It is not often that an opportunity occurs for the formation of an entirely new arm of the fighting services. Cooper was one of the little band, which included, among others, Hardy Wells, Nelson Roche, Stanford, Martin Flack, Treadgold, Stanley Turner, and the late T. S. Rippon, who were concerned with Air-Commodore (now Lieut.-General) M. H. G. Fell, in starting the Royal Air Force Medical Branch. The story of those early days cannot yet be told in full. But it was then that Cooper's infinite capacity for taking pains, organizing ability, tireless tact, and kindness had full play. It was generally hoped and expected that he would occupy the director's chair, but the term of office of the then director was extended, and Cooper had to retire on reaching the age limit. After his period of service at the Air Ministry in the early days of the R.A.F., Cooper served as P.M.O. India, from whence he went to Iraq as P.M.O. On returning to the United Kingdom he was appointed P.M.O., Air Defences of Great Britain, in 1927, which appointment he held until he retired. After his retirement in 1932 he became Clerk and Registrar of the Society of Apothecaries. On the outbreak of war in 1939 Cooper was past the age at which he would be liable to recall. Nevertheless, he volunteered for service, and was appointed P.M.O. Balloon Command. In the 1914-18 war he received the D.S.O. for his services at Dunkirk. He was also made an officer of the Order of St. John of Jerusalem and officer of the Order of the Crown of Belgium. In 1930 he was appointed Honorary Surgeon to His Majesty the King. After leaving Cambridge, Cooper went to the London Hospital and qualified M.R.C.S., L.R.C.P. in 1904, and entered the Royal Navy, from which he transferred to the newly formed R.A.F. He leaves a widow and one daughter, who is herself the widow of a naval officer killed in the last war.

Sir George Henderson, Secretary of the Department of Health for Scotland, opened the new out-patient department at the Dumfries and Galloway Royal Infirmary on Oct. 31, 1947. He recalled that it was almost 200 years since the hospital had been founded, and that it was there in 1846 that the first major operation under a general anaesthetic had been performed in Europe. He reassured his audience that the hospital would not be lost in a huge bureaucratic machine, trying to administer it from far away, but that the local people would have as much say as possible in its running.

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Dec. 20.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included), (b) London (administrative county), (c) Scotland, (d) Eire, (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London), (b) London (administrative county), (c) The 16 principal towns in Scotland, (d) The 13 principal towns in Eire, (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1947					1946 (Corresponding Week)

Poliomyelitis

Notifications of poliomyelitis in the week ended Dec. 27, 1947, were 44 (55) and of polio-encephalitis 4 (5). Figures for the previous week are in parentheses. The following counties have had no notifications in December: Cambridge, Cumberland, Huntingdon, Lines (Holland), the Soke of Peterborough, Rutland, Yorks (N. Riding), Anglesey, Brecknock, Caernarvon, Cardigan, Merioneth, Pembroke, Radnor.

Discussion of Table

In England and Wales there was an increased incidence of scarlet fever 124 and acute pneumonia 118, while a decrease was recorded for measles 170, whooping-cough 38, cerebrospinal fever 31, diphtheria 24, dysentery 23, and acute poliomyelitis 22.

There were only small fluctuations in the local trends of scarlet fever except for increases in Staffordshire 40 and Glamorganshire 35. The only appreciable variation in the returns of diphtheria was an increase of 8 in Lancashire.

Every area except the northern counties recorded an increase in cases of pneumonia, and the largest was that of London 32. The only change of any size in the local returns of whooping-cough was an increase of 30 in London.

The decrease in the incidence of measles was mainly contributed by two counties, Northamptonshire and Yorkshire West Riding with decreases of 168 and 106 respectively. Surrey with an increase of 73 in the notifications of measles was the only area with a large change in the trend of this disease.

Half of the total notifications of paratyphoid and typhoid fever were reported from Lancashire. The chief centres of dysentery were Lancashire 29, London 16, and Yorkshire West Riding 13.

After the slight interruption of last week the downward trend of acute poliomyelitis was continued. The only administrative areas with more than one case of poliomyelitis were Lancashire, Manchester C.B. 3; Warwickshire, Birmingham C.B. 3; Yorkshire West Riding, Sheffield C.B. 2; Oxfordshire, Oxford C.B. 2; Norfolk, Norwich C.B. 2; London, St. Pancras 2; and Devonshire, Dawlish M.B. 2.

An outbreak of paratyphoid B has been reported from Ipswich and the surrounding district, and 22 cases had been admitted to Ipswich isolation hospital up to Dec. 30. A suspected carrier who worked in a bakery has been admitted to hospital.

In Scotland increases were recorded in the notifications of measles 91 and acute primary pneumonia 85; a decrease of 10 was reported in the returns for diphtheria. The rise in the incidence of pneumonia was general throughout the country.

In Eire the chief features of the returns were a decrease of 53 in the incidence of measles and an increase of 12 in the notifications of scarlet fever.

In Northern Ireland the only variation of any size in the returns of infectious diseases was an increase of 12 in the notifications of scarlet fever.

Quarterly Returns for England and Wales

The birth rate during the September quarter was 20.0 per 1,000, compared with 19.7 for the third quarter of 1946 and an average of 15.7 for the corresponding quarters of 1941-5. The number of births registered was the highest recorded for any third quarter since 1920. The infant mortality was 32 per 1,000 live births; this was 9 below the average rate for the third quarters of the ten preceding years 1937-46. Stillbirths represented 22.7 per 1,000 of the total births, and this rate was the lowest recorded in this country in any quarter. The general death rate was 9.0 per 1,000, compared with 9.3 for the corresponding quarter of 1946 and an average death rate of 9.4 for the third quarters of the five years 1941-5. For the first time an estimate of the population by sex and age is given in this quarterly return.

A survey of sickness in the June quarter of 1947 is tabulated in detail according to the number of illnesses, days of incapacity, and medical consultations for age, sex, occupation, and income groups. No critical analysis of the tables is included in the report. It provides a valuable source of information for the research worker, but in its present form of absolute figures it does not give the general reader an immediate picture of the sickness experience of the nation.

Week Ending December 27

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,469, whooping-cough 1,141, diphtheria 157, measles 2,583, acute pneumonia 690, cerebrospinal fever 26, acute poliomyelitis 44, dysentery 53, paratyphoid 22, and typhoid 2.

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

Universities and Colleges

UNIVERSITY OF GLASGOW

Stanley Alstead, M.D., F.R.C.P., F.R.F.P.S., has been appointed Regius Professor of Materia Medica and Therapeutics in the University in succession to the late Prof. Noah Morris, M.D., F.R.C.P., F.R.F.P.S.

UNIVERSITY OF DURHAM

John Bright Duguid, M.D., professor of pathology and bacteriology in the University of Wales, has been appointed to the Chair of Pathology, King's College, Newcastle-upon-Tyne, and to the Department of Pathology in the Royal Victoria Infirmary.

UNIVERSITY OF LONDON

The title of Professor of Bacteriology in the University has been conferred on the Rt. Hon. Lord Stamp, M.B., B.Ch., in respect of the post held by him at the British Postgraduate Medical School.

UNIVERSITY OF LIVERPOOL

The Council of the University has appointed John Tertius Morrison, O.B.E., M.B., F.R.C.S., as full-time Dean of the Medical Faculty, in succession to Prof. T. B. Davie, M.D., F.R.C.P.

The following candidates have been approved at the examinations indicated:

M.D.—S. Bender, D. M. I. Freeman, J. D. King, Teresa Lightbound, M. G. McEntegart, R. C. Nairn.

M.Ch.Orth.—H. G. A. Almond, G. S. Colvin, J. J. Commerell, M. D. Desai, J. Dickie, W. H. Fahmi, C. J. Kaplan, J. G. Kerr, H. K. Lucas, T. B. McMurray, B. F. Miller, N. H. Morgan, A. G. O'Malley, G. V. Osborne, W. Parke, B. Polonsky, T. Price, G. I. Roberts, V. R. Thayumanaswami.

FINAL M.B., Ch.B.—Part III: A. J. Borkin, H. C. Endbinder, W. P. Wilson. Passed in separate subjects: G. D. Currie (Medicine, Surgery), G. Frew (Medicine, Obstetrics, and Gynaecology), J. C. Humber (Surgery, Obstetrics, and Gynaecology).

D.P.H.—Part I: H. O. M. Bryant, A. T. Burn, R. L. J. S. Derham, Jean M. Frazer, E. N. Hugh-Jones, D. E. Jayatunge, D. B. Kennedy, J. D. Munroe, Joan E. M. Potts, R. V. L. Rudolph, R. G. Thomas.

CERTIFICATE IN PUBLIC HEALTH.—A. Griffith.

ROYAL COLLEGE OF PHYSICIANS OF LONDON

The Royal College of Physicians of London is giving a course of postgraduate lectures in medicine from Feb. 2 until March 25. There will be approximately 26 lectures. The full programme is not yet complete but preliminary details can be obtained from the College. The inclusive fee for the course is £7 7s. and the total entry will be limited to 200. Fees are payable in advance and must be received at the College (Pall Mall East, S.W.) by Jan. 26.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

A course of lectures on anatomy, applied physiology, and pathology in their application to dental surgery will be held at the College (Lincoln's Inn Fields, London, W.C.) daily from Jan. 12 to Feb. 6 (Saturdays and Sundays excepted), and a course of lectures on general, oral, and dental surgery will be held at the College daily from Feb. 9 to March 5 (Saturdays and Sundays excepted).

The admission fee for each course is £12 12s.; Fellows and Members of the College and Fellows and Licentiates in Dental Surgery will be admitted for £10 10s. Admission cards may be obtained from the secretary of the Faculty of Dental Surgery at the College.

An Order in Council entitled the Dangerous Drugs Act (Application) Order, 1947, came into force on Jan. 1. Its effect is to bring under the control of the Dangerous Drugs Acts and Regulations the following drugs and preparations, which have not hitherto been so controlled: Amidone, its salts, and any preparation, admixture, extract, or other substance containing any proportion of amidone; and methyldihydromorphinone (commonly known as meponon), its salts, and any preparation, admixture, extract, or other substance containing any proportion of methyldihydromorphinone. It is therefore now unlawful for any person who is not authorized either under the Dangerous Drugs Regulations, 1937, or by licence, to manufacture, supply, procure, or possess any of these drugs. Persons who enjoy a general authorization under those Regulations—for example, doctors and retail chemists—must comply with the Regulations regarding the issue of prescriptions and the keeping of registers in respect of these drugs. Any persons or firms (other than those authorized under the Regulations) concerned in the manufacture, sale, and distribution of any of these drugs and preparations must make application to the Under-Secretary of State, Home Office, 1, Horse Office, St. Stephen's House, Victoria Embankment, London, S.W.1, for consideration to be given to the grant of a licence to permit them to carry out their activities.

Medical News

Rowley Bristow Orthopaedic Hospital

The Church of England Children's Society (formerly the Committee of the Waifs and Strays) has decided to rename the St. Nicholas' and St. Martin's Orthopaedic Hospital (Pyrford, Surrey), which the Society founded, "The Rowley Bristow Orthopaedic Hospital" as an appreciation of his long and brilliant services to the institution.

Oliver Memorial Fund

The committee of the Oliver Memorial Fund offers an award to the value of £50 to a British subject whose original work is considered to have made the most notable contribution to the subject of blood transfusion during the past five years. The committee welcomes applications as well as communications drawing their attention to suitable candidates. Correspondence, accompanied by a brief résumé of such work, should be sent to Mr. F. W. Mills, National Provincial Bank, Ltd., Holborn Circus Branch, London, E.C.1, on or before Feb. 29, 1948.

Gift for Research

Lord Nuffield has given £50,000 to Lincoln College, Oxford, to found three research fellowships to be known as the Nuffield (Penicillin) Research Fellowships. The gift commemorates the discovery of penicillin's therapeutic properties in the Sir William Dunn School of Pathology, of which Sir Howard Florey, who is a Fellow of Lincoln College, is the head.

Surrey Benevolent Medical Society

The Surrey Benevolent Medical Society, which was founded in 1812, has in its gift four perpetual scholarships to Epsom College as well as several other scholarships for boys or girls at any school approved by the society. It also gives pensions to deserving relatives of deceased members. For many years the late Dr. S. Morton Mackenzie was the honorary treasurer, and in memory of him and of his untiring energy in so successfully managing the financial affairs of the society it was unanimously agreed at the last annual meeting to name one of the scholarships after him. This scholarship will henceforth be called "The Mackenzie Scholarship." Membership of the society is open to medical men in private practice in the county of Surrey. Particulars can be obtained from the honorary secretary, Dr. L. J. Barford, Heather Lodge, Redhill, Surrey.

Joint Tuberculosis Council

At the last meeting of the Joint Tuberculosis Council a new committee was set up to consider and report on the problem of tuberculous patients whose duties bring them into close touch with children. The convener of the committee is Dr. Wilfrid Sheldon. The Council discussed the recent cuts in priority milk for tuberculous persons, and the Secretary was asked to inform the Minister of Health and Food that the cuts were regarded with grave misgivings. In the Council's opinion the amounts of food available to tuberculous persons at home and in sanatoria are at dangerously low levels. Another matter considered was the eligibility of tuberculous persons for supplementary financial assistance under the National Assistance Bill. The Council endorsed the opinion of the Tuberculosis Group of the Society of Medical Officers of Health that eligibility for such aid should be based strictly on need and not necessarily on the fact that employment had been given up.

Court of Common Council of the Corporation of London

Major-General R. J. Blackham, C.B., C.M.G., C.I.E., D.S.O. M.D., has been re-elected a member of the Court of Common Council of the Corporation of London for the twenty-third year in succession. For many years General Blackham was the only medical member on the Court, but he was joined in 1941 by Dr. Arthur Westerman, the medical officer of The Charterhouse, who has also been re-elected.

Parkinson's Disease

The Ministry of Health issued the following statement on Dec. 30. "Some weeks ago a report appeared in certain of the lay newspapers concerning a German doctor who was alleged to have discovered a new and effective treatment for Parkinson's disease. As a result of this report a number of inquiries have been made of Government departments regarding the possibility of having the practitioner in question brought to this country to undertake the treatment of selected cases. The matter has been followed up through official channels and it is regretfully announced that the claims made in favour of this particular treatment are without foundation."

University of Athens

The title and status of Emeritus Professor of Medicine in the University of Athens has been conferred on Dr. A. P. Cawadias, O.B.E., F.R.C.P., by Royal Hellenic decree.

Honoured by Chinese Government

The Chinese Government has bestowed the Order of the Brilliant Star upon W. Percival Yetts, C.B.E., D.Lit., M.R.C.S., L.R.C.P., Professor Emeritus of Chinese Art and Archaeology in the University of London.

Export Licensing Control

Under a new order made by the Board of Trade preparations of penicillin have been released from export licensing control. Items that have been added to the export licensing list and for which licences are therefore necessary include: gonadotrophic hormones, testosterone, oestrogens, and bile salts.

Tuberculosis Allowances Scheme

The Minister of Health has authorized an increase in the winter's fuel allowance, under the Tuberculosis Allowances Scheme referred to in paragraph 42 of Memorandum 266/T, from 3s. 6d. to 4s. 6d. a week. This allowance is available from Jan. 4 to May 1.

Health Centres Proposals

The Minister of Health had previously asked local authorities to submit proposals about health centres by Dec. 31. He now cancels this date and will shortly be sending local authorities another circular on health centres.

Wills

Dr. John Crosthwaite Bridge, formerly H.M. Senior Medical Inspector of Factories, left £2,832. Dr. Wilfrid Fawcett, of Worthing, left £6,789, and Dr. Cyril Claude Lavington, of Stoke Bishop, Bristol, left £27,948.

COMING EVENTS

Conference on Mental Health

The National Association for Mental Health (39, Queen Anne Street, London, W.1) has arranged a conference on mental health to be held at Seymour Hall, Seymour Place, London, W., on Thursday and Friday, Jan. 15 and 16, at 10.30 a.m. each day. The subjects for discussion are "Re-adaptation to Life and Work of Persons who have suffered from Nervous or Mental Disorder" (speakers, Drs. G. R. Hargreaves and Donald Stewart); "Methods of Handling Difficult Children in Primary and Post-primary Schools, and Selection and Training of Staffs for Boarding Homes for Difficult Children" (speakers, E. M. Bartlett, Ph.D., and Miss Clare Britton); "Responsibilities of Local Authorities in Relation to Mental Health and the N.H.S. Act, 1946" (speakers, Drs. K. Soddy and Doris M. Odum); and "Education for Mental Health as a National and International Responsibility" (speakers, Brigadier A. Torrie, M.B., Ch.B., and Dr. J. R. Rees). Particulars of conference fees may be obtained from the conference secretary of the association at the address above.

Course on Medical Treatment

The University of Leeds Postgraduate Committee has arranged a clinical week-end course devoted to the subject of medical treatment, and open to general practitioners and others interested, to be held at the General Infirmary at Leeds on Feb. 21 and 22. The fee for the course is £1 1s. Further information and application forms may be obtained from the Senior Administrative Officer, School of Medicine, Leeds, 2.

Edinburgh Refresher Course

A fortnight's refresher course at Edinburgh University begins on Monday, May 3, at 9 a.m. It is intended primarily for demobilized medical officers (Class II) and for insurance practitioners. Fee for graduates not claiming expenses from Government sources, 10 gns.

International Leprosy Congress

The International Leprosy Congress will be held in Cuba from April 3-11, 1948. The last congress was held in Cairo in 1938, and the next should have been held in Paris five years later; the war, of course, prevented this. Dr. H. W. Wade, the president of the International Leprosy Association, and for many years in charge of the Culion Leper Settlement in the Philippines, with 6,500 patients under his care, arrived recently in this country to consult with Dr. Ernest Muir and Dr. Gordon Ryrie, of the British Empire Leprosy Relief Association, about the arrangements for next year's congress.

Postgraduate Course in Uruguay

A postgraduate course in tuberculosis will be held on March 1-13, 1948, at the Instituto de Tisiologia, Montevideo, Uruguay.

Summer School in Health Education

The Central Council for Health Education will hold a residential summer school in health education at "High Leigh," Hoddesdon, Herts, from Aug. 11 to 25, under the direction of Dr. Robert Sutherland. The object of the school is to present the general principles and practice of health education to a wide variety of students, including educational and medical administrators, doctors, and nurses. Lectures are planned to cover the basic knowledge needed by health educators and will include lectures in physiology (by Prof. Samson Wright), psychology (by Prof. James Drever), the biology of infection (by Dr. Robert Cruickshank), and social factors affecting health (by Prof. J. M. Mackintosh). There will be opportunity for attendance at exhibitions of health education material and for nature study expeditions, sports, and hallroom and folk dancing. The inclusive cost of the course per person will be £16 16s. Applications should be sent in before March 31. Those wishing for further details should write to the Medical Adviser and Secretary, Central Council for Health Education, Tavistock House, Tavistock Square, London, W.C.1.

Mental Deficiency

The 72nd Annual Meeting of the American Association of Mental Deficiency and the First International Congress on Mental Deficiency will be held at the Copley Plaza Hotel, Boston, U.S.A., the former on May 18-22, the latter on May 17-22, 1948.

SOCIETIES AND LECTURES

Monday

MEDICAL SOCIETY OF LONDON, 11, Chandos Street, Cavendish Square, W.—Jan. 12, 8 p.m. "More Worthies in Medley's Picture of the Founders of the Medical Society of London." Presidential Address by Mr. W. E. Tanner.

Tuesday

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.—Jan. 13, 5 p.m. "Pneumoconiosis of Coal Miners." Goulstonian Lecture by Dr. C. M. Fletcher.

CHELSEA CLINICAL SOCIETY.—At South Kensington Hotel, 47, Queens Gate Terrace, London, S.W., Jan. 13, 7 p.m. for 7.30 p.m. "Industrial Medicine." Discussion to be opened by Dr. N. Langdon Lloyd.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—Jan. 13, 5 p.m. "Cutaneous Syphilis." Dr. A. C. Roeburgh.

Wednesday

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—Jan. 14, 5 p.m. "X-ray Technique." Dr. C. W. McKenny.

INSTITUTE OF SOCIAL PSYCHIATRY.—At Seymour Hall, Seymour Place, London, W., Jan. 14, 2 p.m. "Therapeutic Social Clubs." Conference and discussion.

Thursday

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East, S.W.—Jan. 15, 5 p.m. "Pneumoconiosis of Coal Miners." Goulstonian Lecture by Dr. C. M. Fletcher.

EDINBURGH CLINICAL CLUB.—At B.M.A. Scottish House, 7, Drumshugh Gardens, Edinburgh, Jan. 15, 8 p.m. "Endocrines in Gynaecology." Dr. E. C. Fahmy.

BRITISH INSTITUTE OF RADIOLOGY, 32 Welbeck Street, London, W.—Jan. 15, 8 p.m. "The Role of Radiology in the Teaching of Anatomy." Prof. A. B. Appleton and Dr. J. W. McLaren.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, 17, Bloomsbury Square, London, W.C.—Jan. 15, 7.30 p.m. "The Place of Pharmaceutical Research in Medicine." A. G. Fishburn, Ph.C., F.R.I.C., D.P.A.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—At 26, Portland Place, London, W., Jan. 15, 7.30 p.m. "Symposium on Leprosy." Opening paper to be read by Dr. E. Muir and followed by Lieutenant-Colonel E. W. O'G. Kirwan, I.M.S.(ret), and Dr. A. R. D. Adams.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, Hyde Park Corner, S.W.—Jan. 15, 4.30 p.m. "Psychiatric lecture-demonstration." Dr. D. Curran.

Friday

FACULTY OF RADIOLOGISTS.—At Royal College of Surgeons, Lincoln's Inn Fields, London, W.C., Jan. 16, 2.30 p.m. "Diagnosis Section Meeting." "Some Surgical Findings in Intrathoracic Disease." Paper by Dr. J. V. Sparks. Followed by discussion.

LONDON CHEST HOSPITAL, Victoria Park, E.—Jan. 16, 5 p.m. "Surgery of the Oesophagus." Mr. D. S. M. Barlow.

ROYAL MEDICAL SOCIETY, 7, Melbourn Place, Edinburgh.—Jan. 16, 8 p.m. "Aetiology and Treatment of Asthma." Dissertation by Mr. D. M. McNab.

Saturday

LONDON ASSOCIATION OF THE MEDICAL WOMEN'S FEDERATION.—At Queen Elizabeth Hospital for Children, Hackney Road, London, E.—Jan. 17, 3 p.m. Clinical meeting.

APPOINTMENTS

Group Captain J. Hutchieson, M.B., B.Ch., D.P.H., has been seconded from the Air Ministry to the Ministry of Civil Aviation as Chief Medical Officer. He will review the Ministry of Civil Aviation's medical requirements and submit proposals.

After qualifying at Queen's University, Belfast, Group Captain Hutchieson joined the R.A.F. in 1936 and has been a senior medical officer on the staff of the Director General Medical Services, Air Ministry, since 1938.

Dr. E. C. Allibone has been appointed Honorary Physician to the Children's Department of the General Infirmary at Leeds from Jan. 1.

Christian William Fraser MacKay, M.B., Ch.B., has been appointed a member of the Executive Council of the Gambia.

The Minister of Health has appointed Miss Elizabeth Cockayne, S.R.N., S.C.M., to be Chief Nursing Officer Designate. Miss Cockayne is matron at the Royal Free Hospital, London.

MILLER, A. A., M.D., D.P.H., D.T.M., Director, Department of Pathology, Preston and County of Lancaster Royal Infirmary.

WARN, J. F., M.D., D.P.H., Medical Officer of Health and School Medical Officer, City of Oxford.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Baldwin.—On Dec. 25, 1947, at Bromhead Nursing Home, Lincoln, to Mabel, wife of Dr. R. B. T. Baldwin, a daughter—Janet Rae.

Edwards.—On Dec. 3, 1947, to Ivan (née Carson), wife of Dr. M. D. Edwards, "St. Margaret," Crawfordsburn, Co. Down, a son—Robert Carson.

Hamilton.—On Dec. 26, 1947, at Lynfield Nursing Home, Altrincham, to Geraldine (née Grind), wife of Dr. R. S. B. Hamilton, a son.

Harders.—On Dec. 15, 1947, at 12, The Drive, Bounds Green Road, N., to Calharine, wife of Dr. Jacob Harders, a daughter—Carolyn Ann.

Ross.—On Dec. 18, 1947, to Betty, wife of Dr. Kenneth M. Ross of Southsea, a son.

Sutton.—On Dec. 28, 1947, at Sidecup, Kent, to Catherine (née Howard), wife of Dr. P. H. Sutton, a son.

Templeman.—On Dec. 25, 1947, at Buckingham Nursing Home, Leeds, to Anne (née Thompson), wife of Dr. G. H. Templeman, M.B.E., 5, Wynford Grove, Leeds, a daughter.

MARRIAGE

Grace—Cope.—On Jan. 3, 1948, at the King's Chapel of the Savoy, Michael Anthony Grace to Philippa Agnes Loks Cope, only daughter of Mr. V. Zachary Cope and the late Mrs. Cope.

DEATHS

Alexander.—On Jan. 4, 1948, William Alexander, M.B., Ch.B., Priestfield, Keirley Road, Colne, Lanes.

Chisholm.—On Dec. 20, 1947, Donald Chisholm, M.B., Ch.B., aged 46.

Courtauld.—On Dec. 26, 1947, at Perces, Greenstead Green, Essex, Elizabeth Courtauld, M.D.

Cowie.—On Jan. 5, 1948, at Blackbrook House, Bickley, Kent, William Cowie, M.B., Ch.B., aged 76.

Davar.—On Sept. 25, 1947, Framji Edalji Davar, L.M.S., aged 57.

Day.—On Dec. 31, 1947, Frank Herbert Day, M.B., Ch.B., "Inchbrook," Kenilworth.

Fellows.—On Jan. 3, 1948, at The Old Rectory, Church Stretton, Frederick MacFarlane Fellows, F.R.C.S.Ed.

Ferguson.—On Jan. 4, 1948, at 162 Eccles Old Road, Salford, 6, Egerton Allen Ferguson, M.C.P.S.

Fitzgerald.—At Cork, Professor Denis Patrick Fitzgerald, M.D., aged 76.

Greeves.—On Dec. 31, 1947, at The Bosh, Broadstone Dorset, Thomas Neville Greeves, M.R.C.S., L.R.C.P., aged 84.

Hedley.—On Jan. 3, 1948, Edward Williams Hedley, M.B.E., M.D., The Cottage, Thursley, Godalming, aged 74.

Jones.—At The Hollies, Merthyr, William Watkin Jones, M.D., J.P., aged 82.

Katham.—On Dec. 28, 1947, at 52, Penn Road, London, N., Harold William Katham, M.R.C.S., L.R.C.P.

Lefevre.—On Dec. 21, 1947, at Studley House, Longton, Stoke-on-Trent, George Louis Lefevre, M.B., Ch.B., beloved husband of Elizabeth H. Lefevre.

Leighman.—On Jan. 3, 1948, at Bearhill, Brechin, Angus, Thomas Arthur Leighman, M.D., J.P., aged 87.

McLinden.—On Jan. 3, 1948, at Marcroft, Ripponden Road, Oldham, William Richard McLinden, M.B., Ch.B., aged 53.

Nathan.—On Dec. 30, 1947, at 122, Sussex Way, London, N., Albert Nathan, M.R.C.S., L.R.C.P., aged 46.

Parsons.—On Dec. 18, 1947, at Fairfield, 2, Rockleaze, Bristol, Henry Frank Parsons, M.R.C.S., L.R.C.P.

Robb.—On Jan. 2, 1948, at 1 Windsor Terrace, Dundee, John James Robb, M.B., F.R.C.S.Ed.

Rutherford.—On Dec. 31, 1947, at 27, Browning Road, Worthing, George Louis Rutherford, M.R.C.S., L.R.C.P., aged 78.

Saunders.—On Dec. 31, 1947, at Bickington, Cecil Sealife, M.D., Lieutenant-Colonel, P.A.M.C., retired.

Seaham.—On Dec. 22, 1947, at Fribourg, Switzerland, Frederick Seaham, M.D., aged 77.

Seymour.—On Dec. 22, 1947, at 2, Belton Avenue, London, N.W., Robert George Seymour, M.B., M.S., aged 74.

Waller.—On Dec. 22, 1947, at Hospital of St. John and St. Elizabeth, London, N.W., Frank Henry Waller, M.R.C.S., L.R.C.P., aged 74.

Waller.—On Dec. 22, 1947, at 10, St. John's Road, Kent, John Hewson Waller, M.B., Ch.B., aged 74.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of these questions and answers which seem to be of general interest.

Prevention of Ophthalmia Neonatorum

Q.—What is the best routine to adopt in order to prevent ophthalmia neonatorum?

A.—The fundamental fact in the prophylaxis of ophthalmia neonatorum is that a healthy mother cannot infect her baby, while an affected mother exposes the baby to that danger. The prophylaxis of ophthalmia neonatorum therefore centres, in the first place, on the mother rather than on the baby. In days gone by gonorrhoea was regarded as almost exclusively the cause of ophthalmia neonatorum. Present-day statistics show that gonococcal ophthalmia neonatorum accounts for not more than about 20 to 25% of the cases—compared with staphylococcal ophthalmia neonatorum and the form of the affection due to a virus which account for about 35 and 30%, respectively. The prophylaxis of ophthalmia neonatorum is therefore a matter of eliminating maternal infection and not merely maternal gonorrhoea. The best routine measure to be adopted involves intensive antenatal care, and the elimination of leucorrhoea in the expectant mother. For the baby Credé's method is a useful but not a totally adequate measure. The older statistics summarized in Sydney Stephenson's *Ophthalmia Neonatorum*, 1907, are conclusive evidence that the introduction of the Credé procedure greatly reduced the incidence of this disease. But it is also clear that it was no foolproof measure entirely eliminating the affection. Sorsby has shown (*Ophthalmia Neonatorum*, 1945, Hamish Hamilton) that in spite of the rigorous use of the procedure some 0.1% of a babies develop gonococcal ophthalmia neonatorum.

The traditional Credé procedure consists of two distinct parts. Swabbing of the eyelids as soon as the head is born and before the eyes are opened, and rigid avoidance of contaminating the face or eyes with the bath water in which the baby has been washed, are measures that may be regarded as asepsis. The instillation of silver nitrate or other agents is an attempt at antiseptics. There is some evidence that the omission of the antiseptic component tends to raise the incidence of ophthalmia neonatorum. The evidence is, however, not conclusive, and would appear that other agents than silver nitrate are at least as efficacious. In the series reported by Sorsby the incidence of ophthalmia neonatorum when argyrol or protargol was used was lower than that in births where silver nitrate was the agent. Whether the difference is statistically significant it is impossible to decide, as so many other factors have to be taken into account. On the other hand, there was a rather higher incidence when mercury perchloride and acriflavine in castor oil were used. It would appear that there is no conclusive evidence that the antiseptic component has any definite value, and it is still less certain whether any particular antiseptic is better than another. The recent suggestion that sodium sulphacetamide might replace the traditional antiseptics is ill founded. In the first place, there is no conclusive evidence that the sulphacetamides locally are of value. Secondly, the momentary action obtained by the instillation of one or two drops that are rapidly washed out from the eye can hardly be expected to achieve much; sulphonamides locally certainly do not sterilize the infected conjunctival sac as a pre-operative measure. Penicillin, though of undoubted value locally, is again unlikely to achieve disinfection of an infected conjunctival sac by momentary contact.

In view of these observations it would appear that the aseptic component rather than antiseptics is the essential aspect of the Credé procedure. Reliance must therefore be placed on swabbing the lids as soon as the head is born and before the eyes are open, and avoidance of any possible sepsis being carried to the face or eyes. It is safe to assume that the conjunctival sac of the newborn baby is sterile so long as the lids are closed and that the baby will not contract ophthalmia neonatorum if the conjunctival sac is protected from septic material on the face, in the bath water, and on the linen.

Treatment of Ascariasis

Q.—How would you treat ascari infestation in children?

A.—Probably the most satisfactory method of treating ascari infestation in children at the present time is with hexylresorcinol crystals. The dose recommended is 0.1 g. for each year up to be age of 10. A saline purge is required the night before treatment, which should be given on an empty stomach, and a further purge two hours after treatment. No food should be taken for five hours. The treatment can be repeated in five days. If the drug is given in capsules, these should not be chewed, as they are liable to cause erosion of the buccal mucous membrane. Apart from this the treatment is non-toxic, though the drug occasionally acts as a gastro-intestinal irritant.

Alternatives to Cod-liver Oil

Q.—In the case of a child who tolerates calciferol but will not take cod-liver oil how can vitamin A be supplemented other than by carotene tablets, which are expensive? What is the vitamin-A content of freshly extracted raw carrot juice?

A.—Alternatives to cod-liver oil are: (a) Vitaminized oil, B.P.C., containing 1,000 units of vitamin A and 100 units of vitamin D per gramme. Dose: 3 to 6 ml., or approximately 1 to 2 small teaspoonfuls, daily. (b) Emulsion of vitaminized oil, B.P.C., containing 50% of prescription a. Dose is twice that of a. (c) Extract of malt with vitaminized oil, B.P. Contains 15% of prescription a by volume. Dose: 20 to 40 ml., or approximately 5 teaspoonfuls to 5 dessertspoonfuls, daily. (d) Ministry of Food cod-liver-oil compound with added vitamin D, which contains 1,000 units of vitamin A and 200 units of vitamin D per gramme. Dose: 1/2 teaspoonful up to 6 months; over 6 months, 1 teaspoonful. (e) Concentrated solutions of vitamins A and D, B.P. Dose: 2 minims (0.12 ml.) daily.

These quantities will provide the optimum daily requirements of vitamins A and D. If proprietary preparations are used, care should be taken that a dose is given providing approximately 3,000 to 6,000 units of vitamin A and 600 units of vitamin D daily. The vitamin-A content of carrot juice is approximately 540 units per ounce (28.4 ml.)

Transplantation of Ureters

Q.—What treatment should be advised for complete epispadias in a boy where the symphysis pubis is normal and there is no sphincteric control of the bladder? At what age would it be advisable to consider transplantation of the ureters? Can anything be done to keep these patients dry (portable urinals have proved unsatisfactory), and are there any special schools where they could be educated?

A.—The majority of surgeons would advocate transplantation of the ureters for such a case. The usual age for operation is about 3 or 4 years. The earlier the age the greater are the technical difficulties, owing to the smallness of the structures involved. Even at the age of 4 years difficulties are encountered, and it would be preferable that the operation should be done by a surgeon with experience of abdominal work in children. There seems to be no satisfactory method of keeping these patients dry, and no special schools where they can be educated.

Treatment of Parkinsonism

Q.—(a) Have there been any further new developments in the treatment of Parkinson's disease? (b) What is the new treatment of Parkinsonism recently reported by Sigwald, Bovet, and Dumont?

A.—(a) Belladonna, hyoscine, hyoscyamine, atropine, etc., remain the most useful palliative measures in the treatment of Parkinson's disease.

(b) In the *Revue Neurologique* (1946, '78, 581) these authors state that they have had good results in the treatment of Parkinsonism with 2987 R.P., which is the chlorhydrate of diethylaminoethyl-N-thiodiphenylamine. So far as the writer knows this is the first published report on the clinical action of this drug, which is not yet available in this country.

Enlarged Labia Minora

Q.—It is often said that large labia minora in women are caused by masturbation. Is there any adequate support for this statement?

A.—Repeated manipulation or stretching of the labia minora can result in their permanent enlargement. It is customary among the women of some primitive tribes to produce gross hypertrophy of the nymphae by such means. Masturbation, therefore, and indeed any source of chronic irritation, can in theory result in hypertrophied labia, but it is probable that the importance of such causes is frequently exaggerated. It is impossible to prove, if only because a patient's denial of masturbation is not usually to be accepted, but it would appear that the condition is most often a developmental anomaly. This view is supported by the following observations: (a) the hypertrophy not infrequently affects one side only; (b) it is found in women in whom there is no other reason to suspect masturbation; (c) it is often not seen in cases where masturbation is admitted. It should be added that when hypertrophied labia and masturbation are associated it may be difficult to say which is the cause and which the effect.

Absent Palatal and Corneal Reflexes

Q.—What is the significance of absence of palatal and corneal reflexes—together or separately? I have seen these signs in hospital in cases of hysteria and also in apparently normal patients.

A.—Both the palatal and the corneal reflexes may be unobtainable—either separately or together—in cases of hysteria. No serious significance is necessarily to be attached to a failure to elicit these reflexes. Nevertheless a unilateral absence of the corneal response may be an important sign, indicating some interference with the trigeminal nerve or the fillet. Loss of the palatal reflex on one side or both may, of course, be an indication of loss of function of the 9th or 10th cranial nerve.

Piercing the Ears

Q.—May I have particulars of the technique of piercing the ears?

A.—Under local analgesia the lobe is transfixed with a wide-bore hypodermic needle. Through this hole a gold ring (hinged and with a sharp point) is introduced. In three months the wound will be epithelialized. (The rings can be obtained from a good firm of instrument-makers.) See also an earlier reply (1944, 2, 615 and 806).

Testosterone Propionate

Q.—(a) Is there an oral preparation of testosterone propionate? (b) Is local application of an ointment containing testosterone propionate to undeveloped genitalia in an adult female likely to promote normal development, and is such a preparation available?

A.—(a) Testosterone does not act by mouth, but methyl testosterone does. It is available in 5-mg. tablets, and from three to six may be given daily. (b) The answer is in the negative. It would also be in the negative if the question involved testosterone given by injection. There is available a preparation of testosterone in the form of an ointment, but it is not satisfactory for most purposes.

Fitness for Work in Compressed Air

Q.—What outstanding factors would determine a man's unfitness to work in a compressed-air atmosphere?

A.—The hazards of work in compressed air vary primarily with the pressure, but the general view is that the following conditions would prejudice a candidate for such employment: age exceeding 40 (for first employment) or below 20; obesity; disease of the heart, lungs, or kidneys; otitis; rhinitis or sinusitis; the common cold; alcoholism. Apart from care in the selection of men for work in compressed air, re-examination at frequent intervals is advisable.

NOTES AND COMMENTS

Expression of Placenta.—Dr. W. KEVERALL MCINTYRE (Launceston, Tasmania) writes: May I be allowed to comment on the answers given in your "Any Questions?" column (Aug. 2, 1947, p. 195, and Oct. 25, 1947, p. 679) on the removal of placenta by injection of the umbilical vein and on expression of placenta? The replies stated that injecting the cord is a "time-consuming" method and is applicable only when the condition is not complicated by haemorrhage and that "this appears to be effective in only a few cases."

For many years I have given 0.5 ml. of "pituitrin" intramuscularly as the head is being delivered, and I consider this useful; but the more recent practice of intravenous injection of ergometrine seems to give better results. Even so, I still find the cord injection has a very definite use in third-stage difficulties.

During the last eight years I have proved many times that in a large percentage of cases of retained placenta, particularly those due to uterine inertia, a rapid injection of hot saline into the umbilical vein not only controls haemorrhage but also stimulates its spontaneous expulsion unless complicated by hour-glass or other contraction ring. If the injection is begun 12 in. (30 cm.) from the vulva, the temperature falls about 10° F. (5.5° C.) in the placental tissues, so that I usually have the saline at about 125° F. (51.7° C.), increasing or decreasing this according to the length of the cord. It is not a "time-consuming" method if the simple apparatus is ready, autoclaved for immediate use. As advocated by Currie, a "sterilendum" enema syringe is much more efficient and expeditious than a "large-sized syringe."

In any properly equipped maternity hospital a two-pint (1.14-litre) jug of hot saline can be prepared in two or three minutes, and the large-bore nozzle or needle of the syringe can be inserted into the vein and the solution injected rapidly—actually it takes me less than two minutes to inject two pints if that amount is required. Frequently uterine response to the hot uterine douche and to the rapid increase in the bulk of the placenta is sufficient to control haemorrhage and expel the placenta before the injection of the two pints has been completed. It is of particular value in cases of atonic uterus in which there is a tendency to steady haemorrhage (even though the amount of blood lost may not be immediately alarming) and the placenta cannot be expressed because of the inertia. If the retention is due to a contraction ring or to a partial (or complete) placenta accreta, one does not expect the injection to expel the placenta, but it will, as I and other of my colleagues have demonstrated over and over again, control the haemorrhage and allow its natural removal later when the ring relaxes. If this has to be done manually, the firm engorged placenta is much more easily handled and removed.

I would suggest that your correspondent, if he sees this rather belated comment, should read the articles¹⁻⁴ for details of this simple technique.

In my private practice I have carried out this procedure for various reasons 182 times in my last 3,000 deliveries. I frequently inject the cord if there has been intrauterine interference in the second stage (manual rotation, high forceps, etc.) or third-stage inertia following prolonged labour, or in certain cases who have had post-partum haemorrhage or manual removals in previous deliveries. Of these 182 cord injections, 154 were successful (81%)—in 50 the placenta was spontaneously expelled during the injection, and in 104 immediately or a few minutes afterwards—28 cases were classed as failures, though in many of these the haemorrhage was controlled and the placenta expressed later. Ten (0.33%) had to be completed by manual removal—two of these had a partial placenta accreta and four had definite contraction rings confining part or all of the placenta. In 1,350 previous cases I had done 18 manual removals (1.3%).

If the value of the technique is understood—and correctly practised—and the simple apparatus is always ready for immediate use, it is not as "time-consuming" as changing gloves and other precautions which should be taken before a manual removal is carried out. It is a safe and easily performed hot intrauterine douche, which reduces the amount of blood loss, lessens the chance of infection, and stimulates uterine contractions, so that the placenta is frequently spontaneously expelled. If not, it can usually be expressed soon afterwards.

Ringworm of Scalp.—Dr. R. T. BRAIN (London, W.) writes: While agreeing with the letter of Dr. I. M. Scott (Dec. 27, 1947, p. 1066) I have little doubt that others, like myself, have given much thought to the therapy of tinea capitis. Many new fungicides have been produced, and some were credited with more effective fungicidal action than the older remedies in general use. However, as Dr. Scott pointed out, the effectiveness of the fungicide is of less importance than the penetrability of the substance into the hair shaft and down to

the bottom of the infected follicle. It seemed probable that some of the new wetting and emulsifying agents might overcome this difficulty, and the problem has been studied since June, 1946, in the laboratory of St. John's Hospital for Diseases of the Skin. Dr. Kenneth Crow began experimental therapy based upon the above-mentioned factors in June, 1946, and this work has been continued by Dr. H. Haber and by Mr. Hadgraft, chief pharmacist of the Royal Free Hospital, but one has been delayed publishing results lest it should be thought that the older techniques involving epilation by x rays or thorium X were already obsolete.

Several fungicides were tried, but the most favourable series of reactions occurred with the use of a preparation of phenyl mercuric nitrate. In this series 22 cases have been treated—8 due to *M. audouinii*, 9 due to *M. felineum*, 4 in which the fungus was not cultured, and one endothrix case. Out of the 22 cases 17 (77%) were cured, the average treatment period being two months, and the criteria of cure a period of repeated observation over two to three months.

A new series of cases has now been started using salicylanilide and so far the results are encouraging. The penetrating base consists of a mixture of carbo-wax with Crill No. 6 containing phenyl mercuric nitrate. It should be pointed out that much work on similar lines has been done in America, particularly in New York, by McKee, Hermann, and Karp and other co-workers. Details of the researches at St. John's Hospital will be published shortly, but it was thought desirable to make this comment and the cautious observation that it is hoped that from this and similar researches it may be possible eventually, but not yet, to avoid the troublesome techniques of preliminary epilation in the treatment of ringworm of the scalp.

Thoraco-Lumbar Splanchnicectomy.—Mr. FRANCIS E. STOKES (Liverpool) writes: You have condensed my short note on a "New Incision for Splanchnicectomy" read before the Liverpool Medical Institution into three lines (Dec. 27, 1947, p. 1052). The result is somewhat misleading, and lest I should be accused of plagiarism I hasten to correct a false impression. The incision described is not new but is an extension of Fey's thoraco-abdominal incision for the approach to the upper pole of the kidney. As far as I am aware however, the use of this incision has never been advocated for thoraco-lumbar splanchnicectomy, all the standard incisions for this operation being placed more posteriorly.

Windows in Plasters.—Dr. DAVID A. HERD (Leeds) writes: The following is a simple method which I have used for several months and one which may be of interest to your readers. All that is required is an ointment box large enough to completely encircle the ulcerated area. Remove the lid and base and reduce the side depth to about 1/2 in. (1.25 cm.), at the same time shaping one of the edges to the skin part. Place the collar round the ulcer and apply the plaster-of-Paris bandage. Before the last one is applied I cut down and remove the collar, using the last bandage to smooth off the ragged edges. In this way you are left with a clean, correctly placed window whose edges are slightly elevated from the surrounding skin.

William Russ Pugh: a Pioneer Anaesthetist.—Dr. GEORGE KAYE (Melbourne) writes: The first administration of an anaesthetic in the Australian colonies was performed by William Russ Pugh, of Launceston, in June, 1847. The ultimate history of this pioneer worker is unknown and the Australian medical historians are anxious to elucidate it. The following biographical facts are recorded: William Russ Pugh graduated L.F.P.S. (Glasgow), 1835; M.D. and Ch.D. (Giessen), 1844; F.R.C.S. (Edin.), 1860. He migrated to Van Dieman's Land about 1838. In about 1854 he moved to Melbourne and his name appears on the *Medical Register of Victoria* for the years 1862-73. It is absent in the year 1874, the presumption being one of death or retirement. The Register of Deaths for the years 1872-7, inclusive, does not contain the name of Dr. Pugh; it is therefore possible that he returned to spend his last years in Britain. Should any reader have information as to the fate of Dr. Pugh or of his family, he is invited to communicate with the Curator of the Museum, Australian Society of Anaesthetists, Physiology School, The University, Melbourne, Australia.

Correction.—*Radiology for Medical Students*, by F. J. Hodges, I. Lampe, and J. F. Holt, was named incorrectly in our review columns on Jan. 3 (p. 15).

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JANUARY 10 1948

LONDON COUNTY HEALTH SERVICES UNDER THE ACT

All the personal health functions hitherto performed by the 28 metropolitan boroughs and the City of London will, on the "appointed day," be transferred to the London County Council. The county for this purpose will consist of nine divisions, identical with the educational divisions, each comprising from two to five boroughs. In each division there will be a health committee, with L.C.C. and borough representatives and with six co-opted members out of a total membership varying from 18 to 29. Mr. R. A. Stamp, chairman of the Hospital and Medical Services Committee of the L.C.C., told a Press conference that effective links would be established between these health committees and the hospitals and also the executive council for London so far as general-practitioner services are concerned ("assuming," Mr. Stamp added, "that Mr. Bevan brings off a deal with the B.M.A."). There will also be a link with the health authorities in adjoining county areas.

A Measure of Rationalization

This new arrangement is expected to make possible a good deal of rationalization. At present, for example, the ante- and post-natal clinics and child-welfare centres are unevenly distributed over the county, both geographically and from the point of view of population density, and it will be possible to make good the deficiencies and to have more uniform provision. Hitherto there have been no arrangements between borough councils and general practitioners for the care of expectant and nursing mothers.

A medical officer of high standing will be put in charge of each of the divisions. He will be responsible under the county medical officer for co-ordinating all the personal health services, including the school service. To each division will be allocated from the medical staff eligible for transfer from the borough councils such staff as are necessary to ensure a high standard of service, and new staff will be recruited. A greater degree of specialization will be encouraged, so that medical officers will be given the work for which they are most suited, whether in the maternity clinics or the child-welfare centres or the school service. Reciprocal arrangements will be sought under which medical staff employed by the Council may obtain experience in maternity or obstetrical departments of teaching hospitals. Whole-time or part-time obstetric or paediatric consultants will be appointed.

Health Centres

Ultimately the point of contact between those engaged in the services for the care of mothers and children, and indeed in all the personal health services, will be the health centre, but in view of conditions in war-damaged London and the scarcity of building materials and labour it is recognized that some time must elapse before permanent health centres can be available. The idea is to form sub-areas of about 20,000 population, conveniently demarcated by main roads, railways, or open spaces, and to provide for each such area a comprehensive health centre or group of centres so situated that no one would have to travel more than a mile to get treatment or advice, and at which facilities would be available for all these services and also for general practitioners. The short-term programme (three years) includes the putting up of temporary structures. A list of 15 maternity and child welfare centres having first priority and of 14 having second priority is given.

One proposal which is being explored is to have joint appointments of medical specialists, employed both by the hospital

and by the local health authority, in connexion with the care and after-care of persons suffering from tuberculosis. A scheme is being worked out for an improved voluntary care organization, with the provision of workshops and settlements for patients, and possibly night sanatoria.

Midwifery Service

The number of domiciliary confinements in London in 1946 attended by midwives was 22,145, about one-third of the total births, and of these rather more than half were undertaken by L.C.C. midwives. Council midwives are at present attending an average of 88 confinements a year, and a similar pressure is being experienced by the midwives employed by district nursing associations and hospitals. The shortage of midwives is likely to persist, and some time must elapse before the number of domiciliary confinements undertaken by each midwife can be reduced to the 66 recommended by the Rushcliffe Committee. An intensive recruiting campaign is to be instituted with a view to increasing the existing staff of midwives, whole or part-time, and of district nurses and health visitors.

For the care of premature infants complete sets of equipment, in accordance with a standard list to be devised, will be lent to mothers free of charge for use at home. The establishment of breast-milk banks at convenient points in the county is proposed.

All the existing health-visiting services will be continued by the Council, subject to such rationalization as may be practicable, and expanded and developed as circumstances permit. About 300 health visitors are at present employed directly by borough councils. It is proposed to consult the metropolitan regional hospital boards and the executive council on the co-ordination of arrangements for health visiting with the hospital and specialist services and the general medical services respectively. Preliminary consultations have taken place with the University of London for the establishment of a school for health visitors. Home nursing is provided at present by voluntary organizations, and the Council intends from the "appointed day" to carry out its duties in this respect through the agency of the 32 voluntary district nursing associations working under the Central Council for District Nursing.

All these services—the L.C.C. hospitals, of course, are left out of account, since they will be handed over to the regional boards—are expected in the first year, after allowing for the Government grant, to entail an additional rate of fourpence in the £. From this, however, must be deducted the present cost, whatever it may be, of the borough and other services taken over.

TUBERCULOSIS ALLOWANCES AND THE NATIONAL ASSISTANCE BILL

MEMORANDUM FROM THE JOINT TUBERCULOSIS COUNCIL

Section 5 (3) of the National Assistance Bill provides that "Regulations under this section . . . shall make special provision for blind persons and persons who have suffered a loss of income in order to undergo treatment for pulmonary tuberculosis." Under Memorandum 266/T allowances are payable to certain categories of patients suffering from pulmonary tuberculosis who give up work to undergo treatment. Many other categories of tuberculous patients, not covered by the provisions of Memorandum 266/T, are receiving public assistance under the existing Poor Law. This assistance is given on a basis

of need without reference to the question whether they have "suffered a loss of income to undergo treatment."

In November, 1946, a deputation from the Joint Tuberculosis Council and other organizations concerned with tuberculosis was assured, according to a report of the discussions approved by the Ministry, that the Ministry "fully accepts the view that tuberculosis calls for special provision in the interests both of the patient and of public health"; and also that "the Assistance Board would, it was hoped, be empowered in the new Bill to make payments to *needful* persons under treatment for pulmonary tuberculosis on a scale higher than the normal scale of assistance applicable to the community as a whole."

The wording of Section 5 (3) of the Bill, while differing slightly from that of Memo 266/T, appears to carry over to the new scheme one of its restrictions, and apparently excludes those at present in receipt of public assistance who have *not* "suffered a loss of income" from undergoing treatment. Yet the need of the patient and his family for adequate care and maintenance on a higher level because of the disease is just the same; and a Bill which seeks to abolish the Poor Law should presumably make provision for the tuberculous on a basis of *need*. It may be argued that these cases could be covered by Section 5 (1), which gives power to the Assistance Board to determine the nature and extent of any assistance to a person in need; but, as tuberculous persons are specifically mentioned in Section 5 (3) and conditions there laid down, it would probably be held in a court that the Board was precluded from using subsection (1) to cover cases not eligible under subsection (3).

It is the intention of the Ministry that the higher rate of assistance should be conditional upon the patient's undergoing treatment. This intention is welcomed by most tuberculosis administrators and there is much to be said for it. It should not be agreed to, however, without full consideration of the fact that it subjects the recipient to what might be quite arbitrary decisions as to treatment ordered by one medical officer, and it might be wise to include some right of appeal.

The Ministry is also anxious to restrict the special scale of allowances to cases of *pulmonary* tuberculosis. Tuberculosis medical officers are almost unanimous in condemning this restriction and consider that the need of the tuberculous patient and his family for a relatively good standard of living is as great whether the condition is pulmonary or non-pulmonary. When Memo 266/T was introduced there was a nation-wide outcry against the exclusion from benefit of the so-called "chronics" and of the non-pulmonary cases. The restriction on "chronics" has been removed: it is to be hoped that the restriction on the non-pulmonaries may also be removed. The number of adult non-pulmonary cases is relatively small; the cost of their inclusion would not be a heavy extra burden and would be outweighed by the benefit of the extra safeguard to the health of the susceptible family.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

County Borough Council.—Gateshead.

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Leyton, Radcliffe (limited to future appointments), Tottenham, Wallsend.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Hutton-with-Roby, Portslade, Redditch (restricted to new appointments), Stanley (Co. Durham), Tyldesley.

Scottish Burghs.—Motherwell and Wishaw.

MEDICAL ASSOCIATION OF IRE

Dr. James Francis Fitzsimond, owing to advancing years, has declined it necessary to resign as from Jan. 1 his position as Medical Secretary to the Medical Association of IRE. His successor has not yet been appointed.

HEARD AT HEADQUARTERS

Staggered Remuneration

The experience of a doctor in Germany as recounted to a colleague in America and published in a journal on the other side makes interesting reading for those who are concerned about developments in State medicine. Recently in Germany there has been introduced into panel practice a system of "staggered" remuneration in favour of doctors with smaller practices, so that for the first 500 on their list they receive for each person 4 marks a quarter. (According to the rate of exchange in Germany a mark is now worth sixpence.) For the sixth, seventh, eighth, and ninth hundreds they receive a progressively decreasing amount, ranging from 3.60 to 0.90 marks, and for anything over 1,000 they receive 0.60 marks. This doctor, who has over 1,900 panel patients on his list, has been receiving about 8,000 marks a quarter, but the effect of staggering is to reduce the amount to 3,000. Expenses of practice do not diminish in the same drastic ratio, but it would be to this doctor's interest to reduce his panel practice from 1,900 to 500, in which case he would earn the full 2,000 marks and be able to dispense with a secretary, and his net income would be relatively higher than if he was responsible for three or four times that number of patients. He is not allowed, however, to curtail his panel practice. In this doctor's case his panel remuneration meets his practice expenses and a little over, and he subsists on private practice.

Air Ambulance

Among the usual batch of miscellaneous queries which reached Headquarters the other morning was one from a firm of aircraft constructors who are proposing to fit a De Havilland Rapide as an air ambulance, and inquired what likelihood there is of air-ambulance traffic. In wartime, of course, the air ambulance plays a great role; in peacetime such a service is useful in countries with vast spaces such as Australia, but in a small island like ours its use is more limited. Local authorities at the moment are concerning themselves with normal ambulance services in association with the hospitals under the Regional Boards, but except possibly in such areas as the Highlands and Islands and perhaps the Yorkshire moors the need for air ambulances does not seem very urgent.

A Resolute Council

An observer at the "crisis" meeting of the Association's Council commented on the rapid changes in its personnel which a few years can make. Out of its sixty or more members only eight were members ten years ago, the eight including the present Chairman, the Chairman of the Representative Body, the Treasurer, the chairmen of three Standing Committees, and two other members. It is natural at such a time to think of some of the doughty figures of the past, and of the words they would have uttered and the action they would have taken in the present situation—of J. A. Macdonald and Jenner Verrall, who had to face another Welshman, and of Henry Brackenbury and Kaye Le Fleming at a later time.

Postman's Knock

One would not have been surprised if the staff of the Association had made wry faces when some members of the Council urged that, in addition to publication in the *Journal* of articles analysing the Minister's document, the articles should be sent by post individually to every member of the profession in the kingdom. In an all-in fight, of course, an expenditure of £200 every time on postage alone, assuming that it is only penny postage, does not count, but a more practical difficulty is the obtaining of paper for this vast circularization. A visit to the Great Hall of B.M.A. House, transformed into something like the dispatching department of a large factory, suggested what it means to dispatch even one set of documents to every practitioner. It means addressing one person in every thousand of the population—not a task to be undertaken lightheartedly.

The Home Office announces that Dr. Brian Arthur McCubbin is no longer authorized under the Dangerous Drugs Acts to be in possession of or to supply dangerous drugs.

Correspondence

National Health Service

SIR.—From the word "go" there will be an avalanche of work which will throw a tremendous strain on the profession and is likely to lead to a breakdown unless there is a corresponding increase of man-power (especially in the under-doctored areas) and expansion in every branch of the profession and ancillary services. The Health Service will require a complete administrative machine analogous to that of the fighting Services and with a large number of doctors doing work which is exclusively administrative. The good will of the profession is assured, but if there is a medical breakdown owing to the Service being forced on us before we are ready, then it must be made quite clear that the Government must accept full responsibility.—I am, etc.,

St. Mary Bourne, Andover, Hants.

W. D. KEYWORTH.

Working Hours in the N.H.S.

SIR.—From perusal of recent correspondence in the *B.M.J.* it appears obvious that very many G.P.s are under no illusions about working hours under the N.H.S. It is indeed patent that our work must be materially increased—the mere extension of free (so-called) doctoring to all women and children, apart from any other class of patient, will ensure this. Not only will our clinical work, our visits, and our surgeries be increased but also, no doubt, will the additional paper work which must inevitably descend upon us. To cope with this increased work we will have at the outset less G.P.s than are in practice to-day. For it is an unfortunate fault of any bureaucratic service (such as the N.H.S.) that it must essentially remove many "producers"—i.e., G.P.s—from their active clinical work into non-productive office jobs. To this depletion in our numbers may be added all those elderly G.P.s who are plodding along keeping their practices alive until the "appointed day."

Thus with reduced numbers we shall be left to face a marked increase of work. Now how long will it take to produce sufficient G.P.s to give the required full service?—ten, fifteen, twenty years? At the best we can settle ourselves down to ten or fifteen years of much harder work until such time as some wonderful State-operated doctor-producing sausage-machine has churned out sufficient medical types to fill the gaps. And, to us G.P.s in practice to-day who will have to bear the brunt and hold the fort until this Utopian state is achieved, what is offered?—(a) A remuneration as yet undefined; (b) a pension on which the large majority of G.P.s who are in practice to-day, being between the ages of 35 and 55, will find it impossible to live, as they will have been unable, through no fault of their own, to put in enough years of service; (c) compensation to our widows for the loss of our practices. I say "widows" expressly, for, under pressure of the increased work which one can visualize, few of us will live long enough to see the Minister's cheque. (We might also suggest to the Minister that he should arrange to employ collectors on our behalf who will continue to go and collect the great mass of book debts which will be owing to us on the "day.")

There is little doubt that we who are in general practice to-day are in for a pretty tough time if the N.H.S. is allowed to come along unchallenged. And, alas, apart from "belly-aching" like this in letters to the *B.M.J.*, there appears to be little that we as individuals can do about it. But we can at least attempt to impress upon the B.M.A. that we have a very definite axe to grind and that that axe should be well and truly ground through the medium of the Negotiating Committee.

It is easy to criticize light-heartedly; it is foolish to criticize destructively. May I, therefore, make one respectful suggestion about working conditions which I believe to be constructive and important to the future well-being of G.P.s under any form of service? The evening surgery is to my mind a most evil institution which has become, for some odd reason, accepted as a necessity in the average practice. It has made the G.P. a man apart from his fellows: it removes him from social functions; it debars him from active participation in local affairs whether it be amateur theatricals, chess club, or even attendance in the

local council chamber; most foul of all, it cuts deeply into his domestic life. In these days of earlier entertainments how many G.P.s can ever accompany their wives or families to the theatre or cinema in the evening? In short, this stupid evening ritual precludes the G.P. from all the normal relaxations to which a man may reasonably look forward at the end of a day's work. Here then is my suggestion in improving the G.P.'s lot: let us, whether under N.H.S. or any other service, have an end of evening surgeries; this demand I would like to see incorporated in the B.M.A.'s suggested terms of service in the N.H.S.—I am, etc.,

Glossop, Derbyshire.

H. M. R. WADDELL.

* The remuneration has since been defined and was published in the *Supplement* of Dec. 20 (p. 158).—Ed., *B.M.J.*

Dispensing in N.H.S.

SIR.—A point about a future national health service which appears to have escaped notice, especially with regard to children: at present we all carry stocks of drugs and dispense at any hour. In the N.H.S. we shall presumably not need these, as a prescription will be issued. It is hoped that adequate pharmaceutical arrangements will be made for late calls: at present chemists in this area close at 6.30 p.m. With all our child patients "on the panel" many late bottles of medicine will be required.—I am, etc.,

Cardiff

DAVID SAUNDERS.

Married Doctors in the Services

SIR.—Your answer to my letter on married doctors in the Services (Dec. 6, 1947, p. 133) provokes me to further utterance. The answer of the Service Departments to the B.M.A. Armed Forces Committee is a red herring in the best complacent tradition. I contend that to all intents and purposes "the comparable officer holding a permanent commission" does not exist. To be "comparable" he must be a doctor, married, have one child (or more), and be less than 25 years of age. What man in these circumstances would take a permanent commission knowing that he must keep his family so frugally on half allowances? Thus, the feelings of such an abstract officer are likewise abstract, and this herring is particularly odorous.

To add insult, the Service Departments recognize that financial difficulties may ensue as a result of this unfair pay system and loftily suggest charity in the form of a war-service grant—the Services means test. And then Mr. Alexander's reply to Sir Ernest Graham-Little is on a different theme—not a comparison with the remuneration of the regular officer but with that of "civilians of similar age and qualifications." I would merely say, "O to be one of them again!" But—an afterthought—Mr. Alexander was no doubt referring to the remuneration of the civilian State-doctor, or should I say the State-civilian doctor. Heaven forbid!—I am, etc.,

CONSCRIPTED, R.A.F.V.R.

Petrol Restrictions

SIR.—So, cap in hand, we go to the Minister of Fuel and meekly ask to be allowed to take our cars to the cinema with us so that we may have the privilege of being called out in the middle of the performance. The Minister (thinking, no doubt, "what a lot of fools") has given us what we asked for, and we have written (Dec. 6, 1947, p. 916) a humble address thanking him for his magnanimity. I submit, Sir, that this is not enough. Your correspondents have asked for recreation, and have simply been given the opportunity to do more work. The doctor's leisure is limited to an extent far greater than other workers', and it is essential if he is to be able to make any use of it that he should have a reasonably convenient method of travel at his disposal. The town practitioner may want to go into the country, miles from the nearest telephone; the country practitioner probably wants to go to a town, but he does not necessarily want to spend his time while there eagerly awaiting the bell that will recall him to work. Other workers can do these things: either they make use of their ample week-ends (often starting at 4.30 p.m. on Friday) or they take a day or two off during the week, a procedure probably only too well known to the Minister of Fuel and Power under the name "voluntary absenteeism."

You state that "medical men naturally expect to share with the rest of the community the various hardships to which we are these days all exposed." Why, may I ask? The rest of the community does not share with us the hardship of being on call at any time of any day or night, nor does it share our relatively enormous occupational morbidity and mortality from coronary thrombosis. In fact, by its 40-hour week and its repeated strikes it must be regarded as very largely responsible for its own hardships.

It has been suggested that we should not ask for privileges denied to others. But our special position is already recognized by the law for some purposes—e.g., exemption from jury service (although one day our self-effacing representatives will probably ask for this exemption to be cancelled). I must ask the B.M.A. to abandon its usual pusillanimous methods and to give an ultimatum to the Government that unless more consideration is given to the medical profession in this matter doctors will cease to be available 24 hours a day.—I am, etc.,

Silver End, Essex.

J. W. NICHOLAS.

COMPULSORY RECRUITMENT TO H.M. FORCES OF MEDICAL PRACTITIONERS

The Central Medical War Committee has been notified by the Ministry of Health of the following changes in the arrangements for calling up medical practitioners with effect from Jan. 1.

The compulsory recruitment of medical practitioners for service with H.M. Forces as general duty medical officers shall be confined to those who have not reached the age of 26 years, unless the Central Medical War Committee agrees (or has already agreed) to postpone a practitioner's call-up beyond his 26th birthday on the ground that he is undergoing or about to undergo training for the purpose of acquiring further qualifications or special experience. In such cases the practitioner shall be liable for compulsory recruitment as a general duty officer until he has reached the age of 30 years.

The compulsory recruitment of practitioners for service with H.M. Forces as specialists or graded specialists shall be confined to those who have not reached the age of 35 years.

Association Notices

PHYSICAL MEDICINE GROUP

Dr. F. S. Cooksey (London) and Dr. D. Wilson (Bath) have been elected members of the Physical Medicine Group Committee as a result of a postal ballot held to fill two casual vacancies on the Committee.

FULL-TIME NON-PROFESSORIAL MEDICAL TEACHERS, LABORATORY OR RESEARCH WORKERS GROUP

As a result of a ballot held to fill casual vacancies, the following have been elected members of the Group Committee:

Dr. J. A. Aitken (London)	} London Region
Dr. J. A. Fraser Roberts (London)	
Dr. J. C. Brundret (Liverpool)	
	Manchester and Liverpool Region
Dr. G. W. Harris (Cambridge)	Oxford and Cambridge Region
Dr. W. R. M. Morton (Belfast)	Scotland and N. Ireland Region

AREAS OF BELFAST AND NORTH-EAST ULSTER DIVISIONS

Notice is hereby given by the Council to all concerned:

(1) That the area of the Belfast Division be redefined as follows: The City of Belfast; that part of County Antrim south of, but excluding, Toomebridge, Ballymena, Carnlough; eastern part of County Down.

(2) That the area of the North-east Ulster Division be redefined as follows: That part of County Antrim north of, but including, Toomebridge, Ballymena, Carnlough; the eastern part of County Londonderry.

The above alterations to take effect as from the date of this notice.

CHARLES HILL.
Secretary.

Branch and Division Meetings to be Held

DERRY DIVISION.—At Derbyshire Royal Infirmary, Tuesday, Jan. 13, 8.15 p.m. Mr. W. G. Rose: Breast Cancer; Mr. N. L. Edwards: Uterine Cancer.

KINGSTON DIVISION.—At Atkinson-Morley Emergency Hospital, Copse Hill, London, S.W., Tuesday, Jan. 13, 8 p.m. Clinical evening. Mr. Wylie McKissock, M.S., F.R.C.S., and the staff of the Hospital have arranged to present a series of cases to demonstrate the modern methods of investigation and treatment in neurological surgery.

SOUTH BEDFORDSHIRE DIVISION.—At Luton and Dunstable Hospital, Friday, Jan. 16, 9 p.m. Speaker: Dr. Charles Hill. All medical practitioners in the area are invited to attend.

SUNDERLAND DIVISION.—At Sunderland and Durham County Eye Infirmary, Friday, Jan. 16, 7.45 p.m. Clinical demonstration by members of the staff of the Eye Infirmary. Address by Mr. B. W. Rycroft: Modern Trends in Ophthalmic Surgery.

Meetings of Branches and Divisions

EAST YORKSHIRE BRANCH

The annual dinner was held on Dec. 11, and was attended by some 60 members and guests. Prof. Espinasse, Dean of the Faculty of Science and Deputy Principal of the University College, Hull, proposing the toast of the Association, commented upon the inability of existing medical schools to provide the number of doctors required by a full health service. In disagreement with the Goodenough Report, and feeling that additional medical schools would be required, he hoped that such a school might be developed in association with the institution he represented.

The President of the Branch, Dr. Stenhouse Stewart, in his reply thanked Prof. Espinasse for the continued favour of the College, which from its inauguration had the support of the Branch, and announced that the B.M.A. Prize for 1946-7 had been awarded to Mr. Jack Cherry, now pursuing his further studies at the London Hospital.

The Home Office announces that the Authorities granted by the Regulations made under the Dangerous Drugs Act, 1920, have been restored to Dr. Henry Joseph Constantine Churchill.

STREPTOMYCIN: A VALUABLE ANTI-TUBERCULOSIS AGENT

BY

WILLIAM H. FELDMAN, D.V.M., M.Sc., D.Sc.
Division of Experimental Medicine, Mayo Foundation

AND

H. CORWIN HINSHAW, M.D., Ph.D., D.Sc.
Division of Medicine, Mayo Clinic, Rochester, Minnesota

To find a specific therapeutic substance that will arrest or impede the progress of tuberculosis and permit the intrinsic factors of healing to operate successfully has been the goal of countless investigators since the beginning of the modern era of chemotherapy. Certainly the need for a specific drug treatment to assist in combating human tuberculosis has been and continues to be a compelling one.

During the past decade many infectious diseases have proved to be highly vulnerable to therapeutic attack by a variety of chemotherapeutic agents. Tuberculosis, however, has until recently resisted specific drug treatment successfully. In the quest for an effective substance in the treatment of tuberculosis little, if any, real basis for encouragement was evident until the advent of the sulphonamide compounds.* The observations that sulphanilamide had exerted a slight but definite deterrent action on the pathogenesis of tuberculosis in guinea-pigs prompted additional work with a large number of other sulphonamides in experimental tuberculosis. The results indicated that none of these drugs met the requirements of a therapeutic weapon sufficiently to justify their use in clinical tuberculosis.

Eventually drugs remotely related to sulphanilamide but chemically definitely dissimilar in certain important aspects were found to be greatly superior to any of the sulphonamide compounds in combating experimental tuberculosis. These latter drugs—known commonly as sulphone compounds—were derivatives of 4,4'-diaminodiphenyl sulphone. Among the better-known sulphone drugs that have figured in the recent revival of chemotherapy of tuberculosis are "promin" (known as "promanide" in Britain), "diasone," and "promizole."

Historical Résumé

Since the ability of certain of the sulphone compounds to suppress tuberculosis almost completely in the highly susceptible guinea-pig was so unprecedented, and since the significance of this phase of the recent development of tuberculo-chemotherapy to the present status of the drug treatment of leprosy is seldom recounted, a brief résumé of the development of the more recent antibacterial attack on tuberculosis seems appropriate.

As mentioned previously, the observations concerning the effects of sulphanilamide on the progress of tuberculosis in guinea-pigs suggested that the sulphonamide drugs and related compounds were worthy of further exploration. In October, 1940, Feldman, Hinshaw, and Moses reported the first experimental study of the use of promin in experimental tuberculosis induced by human tubercle bacilli.† The results when confirmed provided sound evidence that the drugs had exerted marked deterrent effects on the progress of a potentially lethal infection. With the recognition of this fact tuberculosis could properly be removed from the

list of infections previously considered resistant to the suppressive action of chemotherapeutic agents.

After this initial observation with promin the effectiveness of several other sulphone compounds as anti-tuberculosis agents was demonstrated (Feldman, 1946b). This phase of the work served to establish firmly the ability of a number of complex synthetic organic compounds to exert a measurable therapeutic effect on infections induced experimentally by human tubercle bacilli.

Parenthetically it is of interest to note that the work with the sulphone compounds, especially promin, in experimental tuberculous infections stimulated an important development in the chemotherapeutic attack on leprosy. Several reports now available indicate definitely that promin and subsequently promizole and diasone have ushered in an important new era in the specific drug treatment of this disease. An objective appraisal of the results up to the present time indicates that this newer therapy in leprosy is definitely encouraging (Faget *et al.*, 1946).

The advent of specific therapy with antibiotics which followed the development of penicillin again focused attention on the possibility of successful chemotherapy of tuberculosis with antibiotic substances. This was not a new approach to the problem of specific drug therapy in tuberculosis by the use of antagonistic substances of bacterial origin. As a matter of fact a report on this form of therapy had been published by Cantani in 1885. A review of the many subsequent reports of different investigators who have explored this approach to the treatment of tuberculosis discloses many antibiotic agents capable of antagonistic action against tubercle bacilli (Feldman, 1946a, 1946b, 1946c; Hart, 1946; Waksman, 1947). However, observations on the range of activity of the substances studied were, with few exceptions, limited to *in-vitro* tests. A notable exception is streptomycin, which, in addition to demonstrating its antagonism to tubercle bacilli in the test-tube, has demonstrated its effectiveness against tuberculous infections (Feldman and Hinshaw, 1944; Feldman, Hinshaw, and Mann, 1945; Youmans and McCarter, 1945). As the search continues, the possibility exists of eventually obtaining not one but perhaps several additional antibiotic agents that will be equal if not superior in potency to streptomycin.

As a result of the information that has accumulated since the first report on the use of sulphanilamide in experimental tuberculosis was published, a chemotherapy of tuberculosis

* For a review of the development of the chemotherapy of tuberculosis the lectures by Feldman (1946a, 1946b, 1946c), by Hart (1946), and by Waksman (1947) may be consulted.

† A few months previously Rist, Bloch, and Hamon (1940) had reported independently a definite antagonistic effect of 4,4'-diaminodiphenylsulphone on tuberculosis of rabbits and guinea-pigs infected with avian tubercle bacilli.

of practical significance has been evolved. At last, after countless disappointments, the practical therapeutics of tuberculous infections has been advanced by a drug of considerable specificity and usefulness. By the use of streptomycin it is now possible for the first time to arrest by specific chemotherapy the progress of several different clinical types of potentially fatal tuberculosis.

Streptomycin in Experimental Tuberculosis

Therapeutic Efficacy.—The effect of streptomycin on the course of experimental tuberculosis in guinea-pigs and in mice is striking. Under prescribed conditions the potency of this antibiotic is sufficient to alter to a marked degree the usual pathogenesis of infections established by fully virulent tubercle bacilli of the human and of the bovine types. It is of much significance that guinea-pigs inoculated subcutaneously with an effective dose of tubercle bacilli will respond to treatment usually in a dramatic manner. Compared with untreated controls, such animals have an extended longevity, and the residual signs of infection either are not demonstrable grossly or microscopically or, if present, are usually inactive lesions characterized by fibrosis, calcification, or other signs of quiescence. In the experimentally infected animals the tempo of the therapeutic effects is relatively rapid. Evidence of deterrent action may be observed 'after three weeks' treatment.

The specificity of streptomycin for tubercle bacilli and its ability to alter the course of otherwise irreversibly fatal infections are convincing as shown by experiments wherein guinea-pigs are inoculated intravenously with large doses (1 mg.) of virulent tubercle bacilli. Tuberculosis established by this procedure usually becomes a rapidly fulminating process within a short time. However, if treatment with streptomycin is started within three to four days after the animals have been inoculated the treated animals will live many months longer than those not treated (Feldman, Karlson, and Hinshaw, 1947). The same therapeutic restraints can also be observed in white mice inoculated intravenously with virulent tubercle bacilli and treated with streptomycin (Youmans and McCarter, 1945).

Considering the exceedingly formidable character of the widely disseminated infection that follows the introduction of tubercle bacilli direct into the venous circulation, one cannot avoid the conclusion that streptomycin is an anti-tuberculosis agent of considerable potentiality (Feldman, Karlson, and Hinshaw, 1947). It is suggested that in the future new substances antagonistic to tubercle bacilli be subjected to trial in tuberculous infections induced intravenously. Such a procedure should provide valuable data for comparison with the effectiveness of streptomycin.

Dosage.—The therapeutic range of streptomycin in the treatment of tuberculous guinea-pigs appears to vary within rather wide limits. In our experience a daily dose of 4 to 6 mg. administered subcutaneously is therapeutically effective for animals weighing 500 to 800 g. Much larger doses do not seem to be more effective. We have found daily doses of 2 mg. inadequate. However, in many infected animals this smaller dose does exert a definite deterrent influence, but the results are, generally speaking, inferior to those produced by doses of greater magnitude. In the treatment of tuberculous mice with streptomycin a daily dose of 5 mg. divided into four injections has proved effective (Youmans and McCarter, 1945).

Frequency of Medication.—In our earlier studies on streptomycin in experimental tuberculosis we administered a daily dose of the drug in four equally divided injections twelve hours apart. Later, as a result of experimental observations (Feldman, Hinshaw, and Karlson, 1947), we found that the frequent administration of streptomycin was not

essential to a satisfactory therapeutic effect. It was observed that daily doses of 6 mg. divided into two equal injections twelve hours apart were adequate. Furthermore, we observed that animals treated every alternate week appeared to receive essentially the same therapeutic benefit as those on a daily schedule of treatment.

We now prefer to administer the drug every twelve hours. However, it is our impression that streptomycin can be given to tuberculous guinea-pigs, with satisfactory results, once daily or perhaps once every second or third day. There is no evidence indicating that its therapeutic effectiveness in experimental tuberculosis is dependent on frequent administration of the drug. Certainly it is not necessary to administer streptomycin every two to three hours to obtain the desired effects.

Toxicity for Animals.—Although the administration of streptomycin to tuberculous human beings usually provokes certain objective signs of toxicity of varying severity, this drug is well tolerated by guinea-pigs and by mice in doses within the therapeutic level. Guinea-pigs treated daily for five to six months have shown a normal increase of weight and size and have at the end of the experiment the appearance of normal healthy animals. What the maximal tolerated dose for guinea-pigs may be is uncertain. So far as we know, doses of streptomycin even in excess of the therapeutic effective dose do not induce demonstrable damage in the liver or kidneys of guinea-pigs or mice.

In some animals, particularly monkeys and dogs, signs of toxicity have been reported (Molitor *et al.*, 1946). In these animals toxicity was indicated by transient anaemia, mild to severe proteinuria, and casts and blood cells in the urine. Dogs receiving streptomycin have been noted to manifest signs of vestibular dysfunction. Disturbance of metabolism of fat in the liver and kidneys of monkeys and dogs has been reported (Molitor, 1947).

Summary of Evidence in Support of Clinical Trials

In reviewing the evidence to justify the use of streptomycin in the treatment of tuberculous patients several facts of considerable significance may be recounted:

- (1) The experimental animal used was the highly susceptible guinea-pig, which has a minimum of intrinsic resistance to infection by virulent mammalian tubercle bacilli.
- (2) The beginning of treatment was delayed usually from two to seven weeks after the animals had been inoculated with tubercle bacilli. Thus the conditions of the experiments were severe.
- Furthermore, the conditions were those of therapy and not of prophylaxis.
- (3) Treatment extended the lives of the infected animals indefinitely.
- (4) In many treated animals there was a reversal of a previously positive to a negative reaction to tuberculin.
- (5) As a consequence of treatment the usual course of the disease was dramatically modified even though the animals had been infected by intravenous inoculation.
- (6) There was a marked tendency for infected tissues to mobilize factors of repair and resistance, and as a result lesions resolved, fibrosed, hyalinized, or calcified. In a word, under the influence of treatment with streptomycin the tuberculous lesions in an infected animal were converted from an advancing destructive process to one of regression and arrest.

The evidence obtained from the experimental studies amply justifies the conclusion that streptomycin is a highly potent antagonistic agent against tuberculous infections in animals.

The favourable therapeutic index of streptomycin in tuberculous guinea-pigs and the further fact that the drug was well tolerated by these animals provided acceptable reasons for extending the investigation to tuberculous patients.

Residual Infectivity after Treatment.—It is our impression that in tuberculous guinea-pigs streptomycin in most

instances exerts its beneficial effects by suppressing the normal growth-progression of the tubercle bacilli rather than by acting in a bactericidal capacity. We have, however, observed infected guinea-pigs, treated for a prolonged period with streptomycin, in which no residual infection could be demonstrated in the spleen by *in-vivo* tests. In addition the same animals failed to react to tuberculin, although at the beginning of treatment sensitivity to tuberculin had been noted (Feldman, Hinshaw, and Mann, 1945).

Although the question is difficult to decide with finality, it seems likely that at least in some infected animals most if not all of the infective bacteria are eventually eliminated as a direct or an indirect consequence of treatment. However, in our experience this is not true in the majority of instances. Even after treatment for many months and in the absence of recognizable alteration of tissue the presence of fully virulent tubercle bacilli can be demonstrated in the guinea-pigs by suitable procedures. For this reason it must be concluded that the major effect of streptomycin on tubercle bacilli is that of a bacteriostatic agent.* It appears that the concentrations of streptomycin which are attained in the blood and tissues of animals and man are too low to have a direct bactericidal effect.

Streptomycin in Clinical Tuberculosis

The bacillus of tuberculosis produces a number of different diseases in human beings. With this fact recognized, it should not be anticipated that any one form of treatment should be equally applicable to all these diseases. However, these several diseases are all caused by the same micro-organism, *Mycobacterium tuberculosis*, and if the organism is so situated as to be exposed to the antagonistic action of streptomycin the suppressive action of the drug should have a certain degree of effectiveness. Studies have shown that streptomycin is not distributed through all tissues of the body in equal concentration (Baggenstoss, Feldman, and Hinshaw, 1947). Furthermore, the mechanical defects which are produced in different structures by the destructive action of tuberculosis will create special clinical and surgical problems which cannot be met completely with any antibacterial agent, regardless of its efficacy (Hinshaw, 1947a).

Miliary and Meningeal Tuberculosis

Generalized haematogenous tuberculosis of human beings most closely resembles the form of tuberculosis which is produced in guinea-pigs and mice experimentally. Such haematogenous forms of tuberculosis as miliary tuberculosis and tuberculous meningitis have in the past been totally refractory to all therapeutic efforts and have had a mortality rate approaching 100%. Until the advent of streptomycin there was no method of treatment which produced even temporary suppression of these diseases or amelioration of the distressing symptoms caused by them.

It is now well established that streptomycin treatment may be effective in bringing about a clinical remission in a considerable percentage of cases of miliary tuberculosis and of tuberculous meningitis (Hinshaw, Feldman, and Pfuete, 1946; Council on Pharmacy and Chemistry, 1947). It remains to be seen how often these remissions may be prolonged and extended to the point at which one is justified in regarding the disease as cured. We have observed remissions which have lasted for more than two years, and we have patients now under observation who apparently remain well and who eventually can be pronounced essentially cured if this favourable progress continues. When miliary tuberculosis and tuberculous meningitis have been diagnosed at an early stage of the disease and have been treated promptly and adequately, more than 50% of these patients may enjoy a complete remission of all symptoms and of all radiographic and bacteriological evidence

of the infection. Unfortunately, some of these patients will suffer from recurrence of the disease process. In those instances in which the recurrent disease is due to a streptomycin-resistant strain of tubercle bacilli no hope of recovery from the second attack should be entertained. It will probably be at least five years before it can be known to what degree streptomycin treatment will reduce the formerly almost universal mortality rate from these diseases. In the meantime, we would emphasize the importance of starting treatment with streptomycin at the earliest possible moment after the diagnosis of miliary tuberculosis or of tuberculous meningitis has been made.

Pulmonary Tuberculosis

This constitutes the cause of more than 90% of all the deaths from tuberculous infection. The wide variability of tuberculous lesions produced in the lungs and the frequency with which spontaneous recovery from pulmonary tuberculosis is realized make the evaluation of any remedy in this form of disease most difficult (Hinshaw and Feldman, 1944).

Several hundred patients with varying forms of pulmonary tuberculosis have received treatment with streptomycin during the past three years in various American hospitals, and certain conclusions are now tenable (Council on Pharmacy and Chemistry, 1947; Hinshaw, 1947b). All physicians who have employed streptomycin extensively in the treatment of pulmonary tuberculosis have agreed that patients with progressive disease whose symptoms have been marked often enjoy relatively prompt improvement of symptoms, with reduction in the amount of expectoration. There are also a decrease of fever and an improvement of the systemic manifestations of pulmonary tuberculosis. Previously progressive disease becomes at least temporarily quiescent under the influence of streptomycin therapy, and this suppression of the acute disease process is quite uniform during the first few weeks of treatment.

The clinical trend after the first few weeks of treatment depends on whether or not the tubercle bacilli are resistant to the effects of streptomycin and whether or not the destructive nature of the disease is such as to prevent its arrest and the disappearance of bacilli during this period of effective action. Some patients continue to improve for many weeks or months, whether or not streptomycin treatment is continued. The physician is occasionally disappointed to observe a reactivation of the disease within a short time after streptomycin treatment has been discontinued. This tendency to reactivation of previously progressive tuberculosis constitutes strong evidence in favour of the thesis that the drug *in vivo* is a truly effective suppressive agent. There is increasing evidence that streptomycin combined with collapse therapy and other forms of treatment may be effective when either one alone would probably fail.

Tuberculous Laryngitis and Endobronchitis

Tuberculous Laryngitis.—Streptomycin has also been found to be useful in some of the most distressing complications of pulmonary tuberculosis which had previously been refractory to nearly all therapeutic efforts. Tuberculous laryngitis has responded to streptomycin treatment (Figs and Hinshaw, 1946) in a very large percentage of cases, and it is now widely believed that use of the drug is clearly indicated in the more severe and acute phases of this tuberculous disease, even when such treatment is likely to achieve only palliative results. Other ulcerating lesions about the oropharynx and tongue respond to streptomycin in a similar manner. In our experience the most spectacular results with streptomycin treatment of lesions in the larynx have been in those patients with maximal laryngeal involvement and with acute forms of pulmonary tuberculosis without extensive cavitation, and in those patients who have tuberculous laryngitis with minimal evidence of pulmonary tuberculosis.

Endobronchial Tuberculosis.—Active ulcerating lesions of the tracheo-bronchial tree, which are being observed with increasing frequency in the United States, have also responded in a uniform manner to streptomycin treatment (Hinshaw, Feldman, and Pfuete, 1946; Council on Pharmacy and Chemistry, 1947). The serious potentialities of this type of tuberculosis would justify streptomycin treatment under many circumstances. The end-result of tracheo-bronchial tuberculosis is often a bronchial

* The question of the action of streptomycin on tubercle bacilli *in vitro* was the subject of a recent report by Smith and Waksman (1947).

stricture as a result of peribronchial fibrosis. It is immediately obvious that bronchial strictures of this type cannot be precluded and will not yield to any type of antibacterial treatment, and if the degree of obstruction is considerable, pulmonary resection is likely to be required if the stricture is so situated as to make such operation feasible.

Tuberculous Sinuses, Lymph Nodes, Bones, and Joints

Tuberculosis of lymph nodes, of bones and joints, and other types of tuberculosis that produce draining cutaneous sinuses have been treated with streptomycin in a sufficient number of cases to indicate that clinical results are satisfactory in a very high percentage of cases (Hinshaw, Feldman, and Pfuetze, 1946; Council on Pharmacy and Chemistry, 1947; Hinshaw, 1947b). Within a few days to a few weeks after starting treatment the drainage of pus ceases and a scab forms over the sinus, and within a few more weeks, when this scab is dislodged, the sinus appears to be healed. If the sinus tract leads to some large accumulation of pus, such as a cold abscess or an empyema cavity, healing is much less likely to occur, and if it does occur there is much greater danger of a recurrence of drainage of pus. It begins to seem probable that large accumulations of tuberculous pus should be drained by wide-open incision as soon as possible after streptomycin treatment has been instituted. This is in contrast to previously accepted surgical practices. It is probable that tuberculous suppuration may be treated in much the same way as suppurative diseases due to pyogenic bacteria have been treated in the past, provided streptomycin treatment is combined with such surgical intervention.

Cutaneous tuberculosis has not been studied sufficiently to warrant the formation of conclusions, except in the case of serofuloderma which is associated with tuberculous draining sinuses (O'Leary *et al.*, 1947). This has been discussed in the preceding paragraph. A few patients with lupus vulgaris have been treated, and have appeared to respond sufficiently well to indicate the need for further studies.

Tuberculosis of bones and joints involves a series of problems almost as complicated as those afforded by pulmonary tuberculosis. It is immediately evident that no antibacterial drug can promote the regeneration of destroyed structures, and a comparison with chronic osteomyelitis appears logical. Experience gained thus far has indicated that the principal uses of streptomycin for treatment of tuberculosis of bones and joints are to prevent progression of the disease and to afford protection during and after surgical procedures on the tuberculous joints. In early forms of tuberculosis of joints involving the synovial membrane alone, streptomycin treatment in itself may be adequate to arrest the tuberculous process and hence to avoid subsequent destructive changes, crippling deformities, and the need for surgical treatment.

Tuberculous Enteritis and Peritonitis

Tuberculous enteritis is another most distressing complication of pulmonary tuberculosis. It now seems that streptomycin treatment of this disease yields a gratifying degree of symptomatic relief very promptly in a large percentage of patients. It remains to be determined how permanent these effects may be, but, even if the results prove to be merely palliative, treatment is well worth while, and in some other instance may be the crucial factor in permitting the eventual recovery of the patient.

Tuberculous peritonitis has appeared to respond to streptomycin treatment in the small number of cases in which this treatment has been applied thus far. Judgment of therapeutic results in this disease is more difficult than in other forms of tuberculosis because of the fact that the diagnosis has usually been arrived at as a result of surgical exploration and because of the fact that surgical exploration in itself is thought frequently to exert a beneficial effect on tuberculous peritonitis.

Use of Streptomycin Before and After Surgical Procedures

The prophylactic use of streptomycin in conjunction with radical types of thoracic surgical treatment is being put to test in a number of institutions in the United States (Council on Pharmacy and Chemistry, 1947; Glover, Clagett, and Hinshaw, 1947). It has already been determined that streptomycin is of little value in the treatment of advanced and chronic tubercu-

lous empyema (Hinshaw, Feldman, and Pfuetze, 1946). Whether better results will be achieved by surgical treatment of tuberculous empyema in combination with streptomycin remains to be ascertained. There is reason to hope that streptomycin treatment may prevent the development of tuberculous empyema; our surgical colleagues have not witnessed tuberculous empyema following intrathoracic operations for tuberculosis when operation was performed in combination with streptomycin treatment, except in a few instances in which operation was carried out after the tubercle bacilli had become resistant to the effects of streptomycin.

Clinical Toxicity.—Streptomycin is a drug of moderate toxicity when compared with such drugs as the sulphonamide compounds, but it is definitely more toxic than penicillin. The toxicity of streptomycin is negligible when the drug is used for brief periods in the treatment of non-tuberculous infections. However, when tuberculosis is treated with streptomycin it probably is necessary to utilize the drug for many weeks, and this results in neurotoxic manifestations which are described later. Our colleague Dr. Karl Pfuetze (Medical Director, Mineral Springs Sanatorium, Cannon Falls, Minnesota) has been interested especially in toxicity of streptomycin and the efficacy of the drug when given in small doses. His studies, which have now been in progress for at least two years, have shown clearly that streptomycin is effective in doses as small as 1 g. a day, and perhaps the dose may be still further reduced in many clinical circumstances. When the total daily dose is 1 g., fewer than 50% of patients experience any toxic manifestations whatsoever, and only a few of these complain to any considerable degree. Even these usually recover when treatment is discontinued (Pfuetze, personal communication).

Dosage

The minimal effective dose of streptomycin has not been determined for the various clinical types of disease, but we would suggest that in tuberculosis the average daily dose be approximately 1 g. for a patient of average weight. McDermott (personal communication) has suggested a dose of 20 mg. per kilogram of body weight, which appears to be a reasonable and effective dose and one which will yield minimal toxic results. In previous communications we have recommended that streptomycin be injected at frequent intervals so as to maintain a constantly elevated blood level of the drug. However, as a result of experiments carried out on guinea-pigs (Feldman, Hinshaw, and Karlson, 1947), mentioned above, we have modified this conclusion, and in recent months we have been treating patients by giving the daily dose in a single injection or by dividing the total dose into two injections administered at intervals of twelve hours. The results seem to be equally satisfactory, and this has greatly simplified the clinical use of streptomycin. It remains to be determined whether these infrequent injections and lower doses will be adequate to produce and maintain remissions in such malignant forms of tuberculosis as tuberculous meningitis and miliary tuberculosis.

In previous publications we recommended that in treatment of tuberculous meningitis streptomycin be administered intrathecally as well as intramuscularly (Hinshaw, Feldman, and Pfuetze, 1946). Studies have not been completed to ascertain whether intrathecal injection alone or intramuscular injection alone may possibly suffice. In view of the severe reactions which have occasionally followed the intrathecal administration of streptomycin in doses of 100 to 200 mg., which we recommended previously, we have recently reduced the amount of streptomycin injected intrathecally to 25 to 50 mg. a day. It seems probable that such intrathecal injections every alternate day may suffice.

In the treatment of lesions of the larynx and tracheo-bronchial tree streptomycin administered by either aerosol or atomizer has often been employed in addition to intramuscular treatment. Recent observations make it seem possible that intramuscular administration of streptomycin alone is adequate for the treatment of these forms of the disease. In the treatment of tuberculous enteritis intramuscular administration of streptomycin is recommended, and it is doubtful if any advantage is gained by the addition of orally administered streptomycin. However, this phase of streptomycin therapy is worthy of further investigation.

Therapeutic Limitations of Streptomycin

Streptomycin, like all other substances of value in chemotherapy, has certain definite shortcomings or limitations.

Antibacterial Potency

Compared with other antagonistic agents effective against tubercle bacilli the antibacterial efficacy of streptomycin against tubercle bacilli is amazingly high. Yet, as was mentioned previously, the major influence of streptomycin on tubercle bacilli in tuberculous infections appears to be that of suppression of the normal pathogenic activities of the organisms. Sterilization of the infective process, even when observed, cannot be attributed to the direct antibacterial action of streptomycin alone. In many instances in clinical tuberculosis during the treatment with streptomycin a marked diminution and eventual disappearance of tubercle bacilli in sputum or other discharges may occur. However, the final elimination of tubercle bacilli from the infected tissues may be dependent only indirectly on the specific action of streptomycin. Most human beings are intrinsically capable of mobilizing mechanisms of resistance and repair which are effective in disposing of tubercle bacilli or inhibiting their aggressive action.

While it would be desirable in the treatment of tuberculosis to have a chemotherapeutic substance of such potency and safety that all tubercle bacilli could be eliminated from the infected host immediately or soon after the administration of a single dose of the drug, the probable results would still be inadequate. In other words, we should distinguish the specific antagonistic effect of the therapeutic substance on the bacterial parasites from the anatomical and purely mechanical factors that were created as a result of the infection. It is illogical to assume that a chemotherapeutic substance, no matter how potent and effective its antibacterial properties may be, can cause in some incredible manner the immediate and complete restoration of tissues that have been irreversibly damaged or destroyed as a consequence of the pathogenicity of the infective agents.

Toxicity*

Toxicity must also be considered as another of the limitations of streptomycin as a specific agent in tuberculosis. Like all other agents used in chemotherapy, streptomycin has certain toxic potentialities. However, compared with most other chemotherapeutic agents streptomycin has a reasonable margin of safety when the treatment of severe types of tuberculous diseases is considered. The most important toxic manifestation associated with streptomycin therapy in clinical tuberculosis is the unusual neurological reaction giving rise to dysfunction of the vestibular apparatus. Rarely, auditory function is impaired when large doses are given for prolonged periods or when impaired renal function interferes with the excretion of the drug. Other toxic reactions that have been noted include erythematous rash, fever, eosinophilia, and abnormal urinary sediments.

The toxic reaction to streptomycin referable to the eighth cranial nerve or its end-organs which results in a reduction of the vestibular function is the most serious and was one of the first evidences of toxicity described (Hinshaw and Feldman, 1945; Brown and Hinshaw, 1946; Fowler and Seligman, 1947). The incidence of occurrence of this untoward effect is rather high. At least 90% of patients receiving a daily dose of 2 g. of streptomycin for more than one month will exhibit symptoms of vestibular dysfunction. If the dose is reduced to 1 g. a day fewer than 30% of patients will experience any subjective symptoms or exhibit any objective signs of vestibular dysfunction. Fortunately in most cases the symptoms largely disappear within sixty to ninety days or longer after treatment has been stopped. The most severe symptoms of decreased vestibular function occur in patients receiving doses of 3 g. or more of streptomycin daily. Restoration of vestibular function or compensation phenomena occur more rapidly and more completely in children and young adults than in persons beyond the age of 50 (Hinshaw, Feldman, and Pfuertze, 1946).

While the possible toxic effects of streptomycin should be recognized and carefully considered, extensive clinical trials indicate that in cases of tuberculosis in which the prognosis is

unfavourable or uncertain the possible toxic effects of streptomycin do not constitute a valid contraindication to its use (Hinshaw, 1947b). In cases of tuberculosis in which the prognosis is favourable under conventional forms of treatment streptomycin therapy should be used only in exceptional circumstances, if at all.

Streptomycin Resistance

One of the most serious obstacles to the achievement of maximal therapeutic benefits from streptomycin in clinical tuberculosis is the problem of streptomycin-resistant tubercle bacilli. Although the problem of drug-resistant microorganisms is not entirely understood there is evidence that this phenomenon represents a selective process dependent on the capacity of bacteria to undergo spontaneous variation or mutation (Demerec, quoted by Selbie, 1946).

In clinical tuberculosis, while the largest proportion of the bacterial population is sensitive to streptomycin before treatment is started, a few variants are present that are drug-resistant in varying degrees (Pyle, 1947). During treatment with a sufficiently potent antibacterial substance such as streptomycin the more sensitive bacterial cells are gradually inhibited and eventually eliminated, while the more resistant cells continue to be propagated. Eventually, if treatment is long continued, there frequently occurs a gradual replacement of the population of tubercle bacilli from one that was predominantly sensitive to streptomycin when treatment began to one that is predominantly streptomycin-resistant. The degree of resistance may be several thousandfold greater than is true of tubercle bacilli sensitive to streptomycin.

In clinical tuberculosis the exact significance of the appearance of varying percentages of streptomycin-resistant tubercle bacilli is somewhat uncertain at the present time. Evidence obtained by animal experimentation shows definitely that infections induced in guinea-pigs by apparently pure cultures of highly streptomycin-resistant strains of tubercle bacilli are not amenable to the therapeutic action of streptomycin (Feldman, Karlson, and Hinshaw—unpublished data; Youmans and Williston, 1946). However, clinically the occurrence after weeks of therapy of some tubercle bacilli highly resistant to streptomycin does not necessarily indicate that the preponderant bacterial population is resistant, and must not be accepted as an indication that treatment may be of no benefit if the need for treatment continues to exist. The fact that patients may continue to improve spontaneously after administration of streptomycin has been discontinued and eventually may become bacteriologically negative (by guinea-pig tests) for tubercle bacilli indicates that treatment may not be required for extended periods.

The time required for the appearance of streptomycin-resistant tubercle bacilli after the beginning of treatment with this substance is variable. Ordinarily, however, the drug-resistant bacteria cannot be demonstrated in appreciable numbers until treatment has been in effect sixty to ninety days. While it is desirable to obtain cultures for the purpose of bacteriological assays for the determination of streptomycin sensitivity* at regular intervals after treatment has been started, there is no adequate practical quantitative method of determining when resistant organisms have gained ascendancy. All available tests are only qualitative, and merely indicate that at least a few resistant bacilli are present. This must not be accepted as convincing proof that the end-point of practical treatment has been reached.

Whether or not the administration of streptomycin should be continued after the bacterial population has become predominantly drug-resistant is at the present time a controversial question. It is our opinion, however, that when the vast majority of bacterial cells are no longer susceptible to the antibacterial action of streptomycin further administration of the drug is unwarranted and may even be deleterious. If at a later time streptomycin-sensitive tubercle bacilli again predominate, and other indications are favourable, treatment with streptomycin may be resumed.

How best to meet the problem of streptomycin-resistant tubercle bacilli is at present one of the most important of

*A report on the toxicity of streptomycin in human beings has been given by McDermott (1947).

*A method for the determination of sensitivity of tubercle bacilli to streptomycin *in vitro* has been described by Karlson and his associates (1947).

the many unsolved problems that confront the experimentalist and the clinician. A logical approach would seem to be to use as the therapeutic regimen a combination of two or more drugs each having a high antagonistic efficacy for tubercle bacilli. Streptomycin utilized simultaneously with some other (as yet unknown) antibiotic might prove effective. Streptomycin combined with sulphone compounds or with other synthetic anti-tuberculosis drugs offers possibilities that are now being explored.

Final Comment

During recent years studies in the antibacterial attack on tuberculosis have yielded results sufficient to change to a considerable degree many of the previously held therapeutic concepts of tuberculosis. Most important, it has been adequately demonstrated that this disease is no longer beyond the range of specific drug therapy. Instead, the vulnerability of tuberculous infections to a chemotherapeutic attack has been established experimentally and clinically. While to date the completely ideal anti-tuberculosis drug has not been reported it seems probable that substances equal or superior in effectiveness to known agents may be found. These possibilities warrant expenditure of great effort, and this search may become one of the most important and exciting adventures in medical research.

In the meantime streptomycin seems likely to become generally accepted as a useful drug in certain types of clinical tuberculosis. It must, however, be used intelligently, with full recognition of its shortcomings and limitations. It should frequently be used in combination with other effective methods of treatment, rather than as a substitute for such proved therapeutic procedures as care in a sanatorium, collapse therapy, and surgery.

CANCER OF THE STOMACH IN ADDISON'S ANAEMIA

BY

W. A. BOURNE, M.D., F.R.C.P.

(From the Royal Sussex County and Hove General Hospitals)

Among some clinicians there is a feeling that patients suffering from pernicious anaemia are more liable to gastric carcinoma than normal individuals of the same age groups. Kaplan and Rigler (1945) suggested that this feeling had statistical backing, and reported (Kaplan and Rigler, 1947) 18 cases of cancer and 17 simple tumours in 259 cases of pernicious anaemia. During the past two years 15 of my own cases have been observed by radiograph and gastroscopy in the hope of detecting carcinoma of the stomach at an early stage. Occasional estimations of the blood sedimentation rate have also been made, since Whitby and Britton (1946) state that the test is of great value in suggesting the onset of carcinoma. Cases were not selected, and there can be no pretence that they form a series. These observations have resulted in the discovery of three cases of carcinoma in patients free from symptoms and clinical signs: one was certainly operable and one probably operable when first detected. One further case has been found to have a leiomyoma. Two others are under particular observation because of a persistently high blood sedimentation rate; one of these has a nodule of uncertain nature in the pyloric antrum.

The cases observed are here tabulated. The total is made up of 11 females and 4 males. Radiological examination consisted of a barium swallow, fluoroscopy, and, usually, film. Gastroscopy was performed with the Hermon Taylor

or Schindler instrument if the radiological report was doubtful, if there was failure to improve clinically, and once when there was a persistently high sedimentation rate in the absence of abnormal radiological findings. The sedimentation rate was determined by Wintrobe's method corrected for anaemia, and was asked for quite at random. It must be emphasized that no patient had dyspepsia when examined.

Case 9

A retired jockey aged 65 was diagnosed as suffering from pernicious anaemia in Berlin in 1937, and had been on liver treatment with satisfactory results thereafter. Though asymptomatic he was x-rayed on Sept. 18, 1945, and the report stated: "There is some rigidity in the prepyloric region which is somewhat suggestive of early scirrhus carcinoma, but it may be due only to fibrosis. If other signs are equivocal, a repeat examination in a few weeks' time would be advisable for comparison." Gastroscopy on Oct. 31 showed that the lower third of the stomach was fixed and pale, with no peristalsis. Laparotomy was performed on Feb. 27, 1946. At this time he

was feeling fit, was putting on weight, had a good appetite with no abnormal symptoms, and nothing abnormal was found on clinical examination. A blood count showed: Hb, 98%; red cells, 5,050,000; colour index, 0.97; white cells, 6,500 (polymorphs 84%, lymphocytes 14%, monocytes 1%, eosinophils 1%); red cells normal.

At operation there was no evidence of neoplasm, though the stomach was not opened. He continued on liver therapy as before until, in March, 1947, he gave a four-weeks history of constant abdominal pain, worse after meals, and relieved by immediate vomiting of undigested food. During this four weeks his appetite had failed, he had lost 10 lb. (4.5 kg.) in weight, and the bowels were opened regularly. There was no paraesthesia. Clinically he was wasted, with a smooth tongue and flat nails. There was no abdominal tumour or lymph-node enlargement. The blood count showed: Hb, 64%; red cells, 3,400,000; white cells, 9,700; colour index, 0.94; the red cells showed a little anisocytosis and no evident macrocytosis. A test of occult blood in stools was positive. An alcohol test meal showed no free HCl, no blood or bile, and no lactic acid. X-ray report stated: "There are huge irregular filling defects in the pyloric portion of the stomach, indicating the presence of a large tumour mass encroaching on the lumen of the stomach." Laparotomy on April 9 revealed a large carcinoma of the pyloric end of the stomach; glands in pyloric region, portal region, and fissure much enlarged. Post-colic jejunostomy was performed. The patient died on April 22.

Comment.—It seems very probable that when first operated on this patient, with radiological and gastroscopic abnormality in the lower third of the stomach, had early carcinomatous change, not detectable surgically. This did not show itself clinically for eighteen months, when, after only a month's symptoms, the diagnosis was certain. Achlorhydria and length of history render the diagnosis of pernicious anaemia probable. Surgical evidence confirms the radiological and gastroscopic impression that the original lesion was in the pyloric region.

Case 14

A housewife aged 75 had been treated for pernicious anaemia for twelve years with monthly liver injections. In May, 1947, she was admitted to hospital with a three-months history of vomiting three or four times daily at no special time, but occasionally after meals. Nausea and retching were frequent, with production of green bile. There was a non-localized gnawing feeling in the abdomen, but no true abdominal pain. One recent diarrhoeic attack occurred lasting 24 hours. She gave a long-standing history of piles with occasional bleeding, and of a productive cough with dyspnoea. She had recently lost some weight and had tended to constipation. There was no family history of anaemia. Clinically, the tongue was smooth, cracked, and shiny, the conjunctivae pale. Nothing significant was found except transient hypertension and crepitations at both lung bases. The abdomen appeared normal and there were no enlarged lymph nodes. Urinary culture was sterile, and the stools were negative for occult blood. A blood count on May 3 showed: red cells, 2,710,000; Hb, 60%; colour index, 1.1; red cells showed marked anisocytosis with macrocytes, microcytes, poikilocytes, an occasional diffuse polychromatic cell, and an occasional cell showing punctate basophilia; white cells, 3,400 (polymorphs 60%, lymphocytes 38%, monocytes 2%).

Intensive liver therapy was started on May 9, when the blood count showed: red cells, 2,550,000; Hb, 60%; colour index, 1.2; white cells, 5,400; reticulocytes, 1.5%. On May 15 the blood count was: red cells, 3,670,000; Hb, 70%; colour index, 0.97; white cells, 9,800; reticulocytes, 9.5%. On May 22 it was: red cells, 4,600,000; Hb, 90%; colour index, 0.98; white cells, 7,700; reticulocytes, 2.5%. A histamine test meal revealed complete achlorhydria; the blood Wassermann reaction was negative.

X-ray reports were as follows:—May 9: "There is some increased opacity at the right lung base"; May 15 (opaque meal): "Stomach is rather small, shows normal tone; peristalsis somewhat diminished; mucosal pattern normal. Pyloric antrum appears to be narrowed, but peristaltic waves pass

through this portion and it is distensible. No evidence of gastric ulcer. Duodenal cap is large, fills out readily, has a normal contour, and is neither tender nor spastic. No evidence of duodenal ulcer."

Gastroscopy revealed small reddish nodular protuberances at the angulus; antral peristalsis and pyloric closure active. Impression, neoplasm.

At laparotomy on May 27 the surgeon was induced to perform a not very extensive resection of the lower third of the stomach. On opening this a nodular area was seen on the mucosa of the stomach on the lesser curve near to the pylorus, not adherent to the outer coats.

Pathological report by Dr. L. R. Janes.—"The suspicious plaque in the stomach wall shows an adenomatoid appearance of the mucosa with increase in the number of the glands and hyperchromatism of the cells. The cellular arrangement in the gland acini is everywhere regular save at one point where, in a single acinus, there is a de-differentiation of epithelium, the cells of which cannot be identified as gastric epithelium. ? Earliest possible malignant change. The muscularis mucosae is prominent and intact."

The patient was discharged on June 27, and is progressing well.

Comment.—The radiological appearances resembled those in Case 9. Gastroscopically, the angulus was clearly abnormal. Histologically, the thin mucosa, with definite superficial intestinal heterotopia, thickens, Prof. Stewart comments, to about five times its depth, with hyperchromatic vegetative epithelium, no doubt proliferating actively. This appearance is probably pre-cancerous, and in a single acinus Dr. Janes now recognizes genuine early carcinomatous de-differentiation. The general picture much resembles appearances described by Waldeyer (1867) at the site of origin of gastric cancers, when, by serial sections, he first clearly showed their origin in the mucosa and not in connective tissues; and is similar to the areas of malignant degeneration in intestinal polyps (Saint, 1927) and to the non-invasive carcinoma *in situ* of the pars pylorica described by Mallory (1940). I feel strongly that it would have been most dangerous to leave the stomach unoperated and that the history of Case 9 would have been repeated. The case must be regarded as one of cancer, and if there is retrospective criticism it is, as Prof. Hardy has said, that the excision was not wide enough.

Case 11

A violinist and violin maker aged 70 was diagnosed as suffering from pernicious anaemia at Middlesex Hospital in 1934 and has been treated continuously since. On May 30, 1947, he was in good health. An opaque meal showed a pyloric antrum somewhat narrowed, but peristaltic waves passed through this region, which is against the presence of malignant neoplasm. Otherwise, nothing abnormal was discovered in stomach or duodenum, though the stomach is small and empties rapidly.

Gastroscopy on June 25 revealed some difficulty in passing the cardia, but nothing abnormal seen in this area. The angulus appeared irregularly nodular and the pylorus indurated and closing irregularly. On Aug. 24 he was admitted for laparotomy, symptom-free. A blood count showed: red cells, 4,970,000; Hb, 94%; colour index, 0.95; Wassermann reaction negative. On the night before operation he developed right-sided pneumonia. A radiograph on Oct. 7 showed lung fields clear except for thickened interlobar septum. Laparotomy on Oct. 8 revealed a large hard malignant ulcer of the antrum invading the peritoneum, with secondary growths in liver, glands of portal fissure, and pelvic peritoneum.

Comment.—This case was an advanced but asymptomatic carcinoma, which might have been detected if x-ray examination had been carried out earlier. The diagnosis of pernicious anaemia made at the Middlesex Hospital is accepted, and appears to be confirmed by the length of history. Radiologically, antral change was more advanced

than in the two earlier cases, but of the same type; and surgically only the lower third of the stomach was involved. Gastroscopy left little doubt of the diagnosis, but, as in some of these cases, infiltration at the angulus probably imitated the pylorus closely.

Other Cases

Case 8 was that of a woman of 60 with a four-year history of anaemia needing continued intensive liver therapy. She was found at operation to have a small stomach, only 2 to 3 in. (5 to 7.5 cm.) in diameter, with a dumbbell-shaped tumour in the fundus; this was removed with difficulty, and consisted of a benign leiomyoma. Case 15 is that of a man of 77 with a one-year history who has a sedimentation rate, repeated at several months' interval, of 30 mm.: normal for the method, 0-10 mm. only. X-ray examination showed a normal stomach, but gastroscopy revealed a reddish nodule on the greater curve of an otherwise (gastroscopically) normal pyloric antrum. This patient is still under observation, though unsuitable for operation without stronger reason.

These cases illustrate the recognized liability of patients with pernicious anaemia to gastric abnormality, and the desirability of watching them from this point of view.

Discussion

The limitations of this investigation are recognized. Swayed by the weight of others' experience (Wilkinson, 1945) and by the apparently negative result of the first case, observations have been more casual than now seems desirable. The results justify further observation. Investigation in these cases is not difficult: the patients are generally placid and co-operative, their stomachs are easy to examine radiologically (Rigler, Kaplan, and Fink, 1945) and gastroscopically, and they tolerate operation well even in the eighth decade.

Of 15 patients examined for gastric lesions while free from dyspepsia, carcinoma has been found in three. In these cases the carcinomatous area was in the lower third, where radiology demonstrated narrowing even in the two cases which were at a very early stage. There seems to be no pathological reason for this general contraction of the pyloric area, though it may be the first indication of carcinomatous change. On the other hand, it may be a permanent characteristic of these stomachs. It was not productive of delay, and is not mentioned by Jacobson and Palmer (1943) in a radiological study of gastric emptying in pernicious anaemia. The lower stomach is not usually abnormal in pernicious anaemia (Magnus and Ungley, 1938), and gastroscopy confirms this. An abnormal antral mucosa, especially when associated with a narrow antral canal, may predispose to malignancy. It is well recognized that the prepyloric area is particularly liable to develop cancer. Cases of pernicious anaemia showing an abnormal mucosa there should be viewed with as much suspicion as hyperchlorhydric cases with prepyloric ulcers. There is reason to believe, also, that simple neoplasms of the stomach are unduly frequent in pernicious anaemia. Carcinoma originating in these may appear in any gastric area, and is characteristically a bulky polypoid tumour. No such case has been found in the small number now reported, though I have records of other casual ones.

Conceivably, therefore, in pernicious anaemia carcinoma may arise in two ways. It is suggested as a basis for further full observation that the commoner prepyloric carcinoma does not arise in localized polyposis but is associated with rather diffuse mucosal changes detectable by gastroscopy at an early stage, and with narrowing of the prepyloric area demonstrable radiologically.

The patients developing carcinoma were all over the age of 60, and had been treated for ten years or more. With

increasing age abnormal stomachs would be expected to become more liable to malignant change; and liver treatment, by keeping patients alive, may predispose to this form of cancer—if liver extract is not a carcinogen (Kaplan and Rigler, 1947).

The cases observed indicate once again how late in the course of gastric cancer symptoms appear. If, however, these cases are operated on early, then, as Mallory (1947) remarks of early gastrectomy for other prepyloric lesions, histological appearances are not infrequently doubtful. To cure more cancers we must alter our pathological, radiological, and gastroscopic criteria so as to present our histologists with precisely this problem. Kaplan and Rigler (1947) urge that watching cases of pernicious anaemia is the main method of achieving this object obvious at the moment, few as such cases are.

Summary

Examination of 15 symptom-free pernicious-anaemia patients revealed cancer in three. Periodical x-ray and gastroscopic studies are strongly indicated in all cases of Addison's anaemia in remission or relapse.

I am grateful to my hospital colleagues, especially to Dr. L. P. Jones, for much help and restraining criticism. I am indebted to Prof. T. L. Hardy for encouragement and advice, and to Prof. M. Stewart for comments on the histology of Case 2.

THE COMPLICATIONS OF MUMPS

BY

DESMOND LAURENCE, M.B., M.R.C.P.
Late Major, N.Z.M.C.

AND

DONALD MCGAVIN, M.Ch., F.R.C.S.
Late Major, N.Z.M.C.

Officers Commanding Medical and Surgical Divisions,
6 New Zealand General Hospital, Japan

In 1946 a few cases of mumps occurred in a military camp in New Zealand just before the departure of a contingent of about 2,000 soldiers for Japan. A number of cases occurred on the ship during the journey, and after arrival of the force in Japan the disease spread rapidly giving rise to a sharp epidemic of 235 cases in seven months. It has since been possible to follow up 208 of these cases and to examine and to interrogate them. This paper is the result of the investigation, which was of particular interest so far as the complications of the disease and their permanent after-effects are concerned. Of the patients 189 were white men, 14 were Maoris, and 5 were white women. There was no difference in the course of disease in the Maoris except that they did not report it until much later in the illness. Except where specially mentioned the figures refer to the 203 men, whose average age was 22 years, the women being considered separately.

We believe the value of this investigation lies largely in the fact that such a complete follow-up was possible so

after the illness, and that any residual disabilities may be considered unlikely to improve further. The average time of follow-up was seven months after the onset, but in individual cases it varied from four to eleven months. Each patient was interviewed, and so far as possible his notes were studied simultaneously.

The commonest mode of onset of the illness was the appearance of parotid enlargement. However, in 54 cases the onset was with general symptoms (tiredness, malaise, headache, etc.), which were present for up to two days before any glandular enlargement. Enlargement of the submandibular glands alone occurred in 13 cases. Orchitis was the only manifestation of mumps in five cases.

Nervous Complications

At the follow-up each patient in the series was directly interrogated for these symptoms: headache, neck stiffness, drowsiness, facial weakness, disturbances of hearing, and acroparaesthesiae. The statements were noted and compared with the case records written at the time of illness.

There had been symptoms or signs of meningeal involvement in 60 cases: 18 patients complained of moderate headache only, and this single symptom is of rather doubtful significance as no lumbar punctures were performed; 36 complained of severe headache and, in addition to marked pain, were drowsy and had a positive Kernig sign or neck rigidity; and six showed a definite meningo-encephalitis, these being recorded below. One man complained of deafness and vertigo, and two men had vague aural symptoms on one side during the early stages of the illness.

Unfortunately, owing to the size of the epidemic and the limited facilities available at the time, lumbar puncture was not performed in some cases in which the results would have been interesting and probably abnormal. Where performed the findings are recorded with the individual cases.

Case Histories

Case 1.—A. J. S., aged 21, noticed the onset of throbbing retro-orbital headache with slight sore throat and swelling below the right ear on Aug. 19, 1946. The swelling increased until the 21st, when he was admitted to 6 N.Z.G.H. He was found to have tender swelling of both parotid glands, more marked on the right, and a small non-tender swelling of the left submandibular gland. By Aug. 25 both submandibular glands had become grossly swollen and tender. Next morning he complained of swelling and pain in the left testicle, and was found to have a well-developed epididymo-orchitis. At 7 p.m. on the same day he complained of frontal headache, drowsiness, nausea, and photophobia. His temperature, which had varied between 98.4 and 100° F. (36.9 and 37.8° C.) rose to 105° F. (40.6° C.) at 10 p.m. Flexion of the neck caused pain in the lumbar region, but no other abnormality was found. On Aug. 27 he felt better but was still drowsy, and he vomited all food and drink. Neck rigidity was still present and Kernig's sign was positive. The enlarged salivary glands were subsiding. The same evening he became more drowsy and disorientated. On examination marked weakness was found in both legs, right more than left, absent knee- and ankle-jerks, and extensor plantar responses. Cerebrospinal fluid examined on the 28th contained 30 mg./l. of protein per 100 ml. and 4 lymphocytes per c.mm. By Sept. 3 he felt quite well and was symptom-free, although examination of his nervous system revealed a marked right-upper-motor-neurone facial weakness, weakness and incoordination of right arm and leg, with normal tendon reflexes and an extensor plantar response on the right. Appreciation of light touch, pain, and temperature was impaired on the right side of the face and body. Position sense was impaired in the right hand. After convalescing for a further two weeks he returned to his unit, where he began to suffer from "dizzy attacks and blackouts." These at first occurred at any time of day when up and about, but by

the end of the year they occurred only if he stood at attention for any length of time. His symptoms were immediately relieved by sitting or by lying down. When examined at this time he still had obvious facial weakness, with slight weakness of grip in the right hand and of dorsiflexion of the right wrist. There was slight sensory impairment to light touch, pain, and temperature over the right face, chest, and arm. The right leg was normal, with a flexor plantar response. The left testicle was slightly smaller than the right. After a month's physical training at a convalescent camp his fainting attacks ceased. Eight months later the patient was completely normal apart from a still apparent facial weakness.

Case 2.—G. H. M., aged 22, was admitted to 6 N.Z.G.H. on July 5, 1946, complaining of a sore throat and swelling under the right jaw for 18 hours. Frontal headache and flitting limb pains had been present for eight hours. Examination revealed a swollen right submandibular gland, marked neck rigidity, and a positive Kernig sign. There was slight weakness of the right arm and leg, with normal tendon reflexes and an extensor plantar response on the right. Temperature was 103° F. (39.4° C.). That evening he became very restless and complained of aching pains all over his body; his headache was worse. The weakness of his right arm and leg became more marked and a left facial paresis developed. Lumbar puncture gave a slightly turbid fluid containing 680 cells per c.mm. (97% lymphocytes, 3% polymorphs); total protein, 100 mg. per 100 ml.; Pandey's reaction positive; chlorides, 659 mg. per 100 ml.; 13,700 white cells per c.mm. (79% polymorphs, 9% lymphocytes, 12% monocytes). On July 8 the patient felt much better, but still had slight neck rigidity. The right hemiparesis and left facial weakness had not improved. On the 10th the left parotid gland became swollen, but his general and neurological condition had improved. He made a rapid recovery and was discharged to his unit, with no abnormal physical signs after four weeks in hospital. When seen 11 months later he had no complaints, and his nervous system was normal except for a mild left facial weakness.

Case 3.—F. B. C., aged 20, developed a frontal headache and bilateral parotid and submandibular enlargement on Aug. 22, 1946. On Sept. 3 he developed bilateral orchitis. Two days later he complained of frontal and occipital headache and his temperature rose to 103° F. (39.4° C.). Kernig's sign was positive. Next day the headache was more severe, with photophobia and neck rigidity, and he had diplopia on looking upwards. No definite ocular muscle paresis could be detected clinically. White blood cells numbered 6,600 cells per c.mm. (60% polymorphs, 36% lymphocytes, 4% monocytes). The diplopia lasted seven days. On Sept. 17 he went to a convalescent camp, where he continued to complain of dull frontal headaches. These continued intermittently for five months, although they may have been partly due to an infected maxillary sinus for which he was being treated.

Case 4.—R. H., aged 22, was admitted to 6 N.Z.G.H. on Aug. 29, 1946, with an enlarged right parotid gland. Next day he complained of malaise, severe frontal headache, and nausea, and he vomited several times. The temperature was 102° F. (38.9° C.). On Sept. 3 he was still vomiting; the temperature was 103° F., Kernig's sign was positive, and the knee-jerks were absent. Marked neck stiffness developed during the course of the day. Lumbar puncture gave a slightly turbid fluid containing 700 cells per c.mm. (95% polymorphs, 5% lymphocytes); total protein, 60 mg. per 100 ml. On the 5th he felt better (temperature 102° F.), and there was slight weakness of flexion of the right hip, knee, and ankle. Knee-jerks were still absent. White blood cells numbered 5,200 per c.mm. (42% polymorphs, 52% lymphocytes, 4% monocytes, 2% eosinophils). His pulse rate fell below 50 on the 14th and 18th days of illness. By Sept. 24 he was quite well and there were no abnormal signs in his nervous system.

Case 5.—A. J. M., age 22, was admitted to 6 N.Z.G.H. on Feb. 18, 1947, complaining of headache and shivering, with pain in the right hypochondrium and nausea for eight hours. Examination revealed tenderness and rigidity in the right hypochondrium and tenderness in the right loin. The psoas sign was positive on the right. Next day he was drowsy

and developed photophobia, slight neck rigidity, and tenderness in the right iliac fossa. On Feb. 20 the left parotid gland became swollen. Lumbar puncture showed: C.S.F. pressure of 160 mm.; 545 cells per c.mm. (99% lymphocytes, 1% polymorphs); total protein, 70 mg. per 100 ml. Pandy's test was positive and urinary diastase normal. There were no abnormal physical signs in the nervous system except a positive Kernig sign and neck rigidity. His headaches ceased gradually over a period of about a month. On Feb. 27 the C.S.F. contained 220 cells per c.mm. (99% lymphocytes, 1% polymorphs); total protein, 50 mg. per 100 ml. Pandy's test was negative. On March 7 he complained of epigastric discomfort after food, and on the 10th the C.S.F. contained 62 cells per c.mm. (all lymphocytes); total protein, 40 mg. per 100 ml. On March 25 a small area of pulmonary collapse developed at the left base, with hilar gland enlargement. This cleared up completely after two weeks, and he was symptomless throughout. The indigestion persisted for several weeks in spite of treatment; it was considered to be largely psychological in origin. Several examinations for urinary diastase gave normal figures. When last seen ten weeks after leaving hospital the patient was quite fit.

Case 6.—J. A. G., aged 21, was admitted to 6 N.Z.G.H. on Sept. 9, 1946, complaining of malaise. The following day both parotid glands became slightly enlarged. On Sept. 12 he developed a right-sided orchitis and next day he complained of severe headache and vomited. On Sept. 15 his speech was slurred and there was marked neck rigidity. Kernig's sign was positive. On the 17th he developed a left facial paresis; there was weakness of his right leg, with normal tendon reflexes and bilateral extensor plantar responses. On the following day the plantar responses became flexor, but his condition was otherwise stationary. The cerebrospinal fluid was slightly turbid and contained 420 cells per c.mm. (98% lymphocytes, 2% polymorphs); total protein, 90 mg. per 100 ml.; Pandy's test positive. By Sept. 30 he had completely recovered except for a slight left-upper-motor-neurone facial paresis. In February, 1947, he had an attack of measles with severe headache. Lumbar puncture performed when the rash was fading (sixth day) showed that the C.S.F. contained 33 cells per c.mm. (32 lymphocytes, 1 polymorph); total protein, 40 mg. per 100 ml. Pandy's test was negative. White blood cells numbered 9,150 (64% polymorphs, 32% lymphocytes, 4% monocytes). There were no physical signs in the nervous system except for the slight left facial paresis, a relic of his previous illness.

Case 7.—F. H. G., a woman aged 27, was admitted to 6 N.Z.G.H. on Sept. 7, 1946, complaining of headache and malaise; there was bilateral parotid swelling, more marked on the left. On the second day she developed a dull peri-umbilical pain with tenderness. Next day the headache became worse and she became drowsy; slight neck rigidity was present. On the ninth day a right facial paresis developed. There was mild bilateral mastitis during the illness. She was discharged fit after three weeks, although the facial weakness was still obvious. At the follow-up seven months later there was still a trace of facial weakness, and the patient complained that she had had amenorrhoea since the illness.

Case 8.—C. O. N., aged 26, developed bilateral parotitis on June 6, 1946. Next day he noticed a slight degree of deafness in the left ear, which became severe during the next 24 hours. There was also vertigo. At the follow-up nine months later he was found to have a pronounced degree of nerve deafness in the left ear.

Discussion

The literature on the nervous complications of mumps is adequately reviewed by Lightwood (1946), Church (1946), and Holden *et al.* (1946). The incidence is reported in various studies as varying from nil to 40%. Meningitis is undoubtedly the most frequent manifestation of nervous involvement in mumps, in addition to which numerous minor and less common syndromes have been recorded less commonly. Generalized mumps-encephalitis with or without fits, diencephalic encephalitis, hemiparesis, tetraplegia, cranial-nerve palsies (especially 3, 7, and 8, acoustic and

vestibular divisions), optic neuritis, bulbar palsy, involuntary movements, and myelitis. From all of these complete recovery is usual, and consequently pathological studies are few. Demyelination of the corona radiata and encephalitic patches in the cerebral cortex and brain stem have been observed. The changes in the C.S.F. have been recorded often and at length, and are well known.

The nervous symptoms and signs are generally said to have their onset at the height of the illness, usually before the development of orchitis. In the eight cases recorded above the onset ranged from one in which the patient reported sick with nervous involvement and possible pancreatitis (Case 5) to one in which there was no nervous involvement (unless the early headache is regarded as such) until the 14th day (Case 3). The average day of onset was the fifth. In most of the cases recorded above it was not possible to localize the encephalitis to a single site, which is what would be expected in this type of disease. Case 1 presented a rather mixed picture, which could be accounted for by bilateral involvement of the corona radiata, more marked on the left. During convalescence the picture of an uncrossed hemiparesis, most pronounced in the face and arms and less severe in the leg, with sensory change over the upper part of the body, supports a subcortical localization, although affection of the brain stem could also account for it.

Case 2 showed a crossed hemiparesis (left face and right limbs), which is most likely to be due to a brain-stem lesion. Case 6 was of considerable interest in that the patient had an abnormal C.S.F. during an attack of measles five months later. It is not known whether the fluid was normal in the interval, but usually it fairly rapidly becomes so after mumps encephalitis, and it would therefore seem that man is constitutionally susceptible to potentially neurotropic viruses or that this susceptibility dates from and is due to the mumps encephalitis. Case 8 showed involvement both the acoustic and the vestibular portions of the eighth nerve. Recovery from the facial weakness in Cases 1, 2, and 7 was still incomplete at the follow-up, and it seems more likely that some permanent damage has been done. Apart from this and the vasomotor instability of Case 6 and the deafness of Case 8, all recoveries from nervous involvement were fairly rapid and complete.

Orchitis

Orchitis occurred in 53 (26%) men—in 17 cases still confined to bed, in 5 at onset, in 6 before report, and in 21 after starting to get up. For the remaining 4 no information was available. The follow-up period was four months in two cases, five months in one case, and between six and ten months for the remainder. The onset occurred during the first week in 34 cases and during the second week in 16. One case developed on the 15th day and two cases on the 22nd day. The disease was bilateral in five patients. Orchitis was the first definite sign in five cases, appearing on the second or third day after a prodromal stage of lassitude and anorexia. In four of these the orchitis was the only clear manifestation of the disease, there being no subsequent parotitis.

In the follow-up 31 cases (57%) were perfectly normal. There was no testicular atrophy, the consistency and the sensation of the testes were unaltered, and sexual activity was unimpaired. In four cases there was or had been some residual pain after exercise, mild in all cases and usually transitory. In two the aching still occurred seven months after onset, and was associated with some degree of atrophy. In the other two there was no atrophy; one man's discomfort had ceased three to four months after onset, while the other's was improving at ten months.

Assessment of atrophy was based mainly on a difference of more than 1/4 in. (0.6 cm.) between the length of the two testes. This criterion is open to certain objections, including some degree of difference between the two sides in healthy people. It was applied only when the unaffected side appeared to be well developed and healthy. In none of the bilateral cases was there any reason to suspect any degree of atrophy. The patients' observations were invited in each case as a rough check. There was no case of complete atrophy in the series. Some degree of difference between the healthy and the affected sides was noticed in 22 cases (42% of those with orchitis), amounting to 1/2 in. (1.25 cm.) in 3 men, 3/4 in. (1.9 cm.) in 10, 1 in. (2.5 cm.) in 7, and 1 1/4 in. (3.2 cm.) in 2. Of these 22 testes 4 were softer than on the healthy side. Testicular sensation was normal in all. A decrease in size after the orchitis had been noticed by 13 patients, no change had been observed by 2, while the remaining 7 had no observations.

Sexual activity, as judged by intercourse, masturbation, or nocturnal emission, was unimpaired throughout the whole orchitis series. It remained unaltered in one man whose other testicle was completely atrophied from a preceding and independent cause; no atrophy of the remaining testis followed the mumps orchitis.

One patient had had an attack of mumps two years earlier, with orchitis on the same side in each attack. By contrast, another man had had orchitis with mumps five years earlier without developing orchitis in his second attack.

Considering the absence of complete atrophy in the series, the fact that 1 in. or more of atrophy occurred in only nine cases and that there was a lack of any impairment of sexual activity, it is doubtful if we are justified in recommending a decompression operation in all cases of mumps orchitis. It might perhaps be advised for those with orchitis of a single functioning testicle or for those with severe bilateral orchitis, though the present small series would hardly justify the latter indication; but for the remainder it is not indicated in the present state of our knowledge.

Other Complications

Pancreatitis and Mastitis.—Some degree of pancreatitis was considered to be present in 16 (8%) of the complete series. Symptoms lasted from one to five days. No sugar was found in the urine of 11 cases tested at follow-up, nor were there any sequelae. One woman complained of tenderness of the breasts during the early part of the illness, and one man had vague fleeting pains round his nipples soon after the onset of mumps.

Cardiovascular System.—Myocarditis has been reported in mumps, and Rosenberg (1945) undertook a full electrocardiographic study, in which he obtained abnormal records in 15% of cases. Although no thorough investigation could be carried out in this epidemic it was thought that it might be of interest to note the number of patients in whom the pulse rate fell below 50. Only 131 pulse charts were available, and 52 showed readings of less than 50 for varying periods, chiefly in the second and third weeks. One of these cases also had an apical systolic murmur which was still present at the follow-up. There were five cases of apical systolic murmur without bradycardia: in only one of these had the murmur disappeared at the follow-up several months later. It is not proposed to attempt to draw any conclusions, as there are obviously insufficient data, but these results seem to confirm the opinion that the cardiovascular system deserves more attention in cases of mumps than it has hitherto received.

Relapse and Second Attack.—Two cases relapsed with recurrence of glandular enlargement after discharge from

hospital. A third patient relapsed with submandibular sialadenitis after an initial orchitis. Eighteen men gave a definite history of a previous attack of mumps and six thought they had probably had mumps before but were not certain.

There were no cases of urethral discharge, pericarditis, arthritis, nephritis, or suppuration of glands, all of which have been recorded as complications of mumps.

Complications in Women.—In one case the disease started with diarrhoea and vomiting, and the patient had amenorrhoea for six months afterwards and felt generally run-down. A second case (No. 7) showed evidence of mild meningo-encephalitis and mastitis. The remaining three cases complained spontaneously of tiredness since the illness—a complaint which was not made by any of the men.

Summary

An epidemic of mumps was investigated with the view of determining the incidence of complications and any permanent after-effects resulting from them. Eight cases of meningo-encephalitis are described. It was found that recovery tended to be slow and that when facial palsy occurred recovery was incomplete.

The incidence of orchitis was 26%. There were no cases of complete testicular atrophy following this complication, but 42% showed minor degrees of atrophy. Sexual activity was unimpaired.

We thank Col. C. R. Burns, senior medical officer of 2 N.Z.E.F. (Japan), for encouragement and permission to carry out this study, and also the regimental medical officers of the units concerned for their help in collecting the men for the follow-up examinations.

FATAL AIR EMBOLISM DURING MASTECTOMY

BY

C. LANGTON HEWER, M.B., M.R.C.P., D.A.

Senior Anaesthetist, St. Bartholomew's Hospital

AND

HERBERT I. COOMBS, M.A., Ph.D., M.D.

Sector Pathologist

Air embolism may be associated with a large number of conditions. The circumstances in which it most frequently occurs are as follows: (1) Gynaecological and obstetrical (often criminal) procedures involving the manipulation of the pregnant or puerperal uterus. Many deaths have been recorded after insufflation of the vagina during pregnancy or the puerperium, and death has even occurred following insufflation of the Fallopian tubes. Placenta praevia is also an especially dangerous condition. (2) Intentional introduction of air or other gas into cavities or potential cavities such as the bladder, joint cavities, paranasal sinuses, and peritoneal and pleural cavities. Perirenal insufflation has given rise to air embolism. (3) Unintentional introduction of air into vessels during transfusions or infusions or into solid organs such as the liver. (4) Operative procedures to the breast, thyroid, lungs, etc. Air embolism may follow injury to vessels by stab wounds, bullet wounds, etc.

The effects of air embolism are very variable in severity, depending mainly on the condition of the patient, the

amount of air entering the circulation, and especially on the rate of access to the circulation. Symptoms may be absent or they may be slight and transitory. On the other hand, death may supervene, and this may be rapid or delayed. A rapidly fatal case which occurred during mastectomy is here described.

Case Report

The patient was a healthy-looking woman of 52 who had a fairly advanced carcinoma of the right breast. At the age of 37 her heart had been examined and it was suggested that she might have a lesion of the aortic valve, but she had remained in good health since that time. On examination the day before the operation no abnormal physical signs could be found in the heart.

A radical mastectomy was performed under general anaesthesia, induction being by intravenous thiopentone and maintenance by nitrous-oxide-oxygen in a closed circuit. A small amount of ether was added during the first ten minutes. The operation and anaesthesia proceeded without incident until the breast had been removed and glands were being dissected out from the axilla. Some haemorrhage took place from the axillary vein, and a few minutes elapsed before a ligature was passed round the vein and tied. At the moment of ligation the patient gave a sharp inspiration and stopped breathing. Simultaneously the colour became grey and the pulse imperceptible. The breathing circuit was at once emptied and refilled with oxygen, and after four or five compressions of the rebreathing bag spontaneous respiration started, the colour became pink, and the pulse returned, although it was poor in volume. The operation was finished with the patient breathing pure oxygen. An intravenous injection of 20 mg. of "methedrine" did not improve the pulse.

As dressings were being applied the colour again faded and the pulse and respiration ceased. Right auricular puncture at first showed a few twitches at the end of the needle, but these soon ceased. Cardiac massage also produced no response, and after about twenty minutes resuscitation was abandoned.

The cause of death was at first thought to be primary cardiac failure, but on further reflection this theory was found to be untenable. The conditions known to predispose to this event were not present. No drug or combination of drugs likely to produce cardiac failure had been given and no reflex stimulation had occurred. Furthermore, cardiac stimulation and massage, although carried out promptly, produced no response. Secondary cardiac failure from advanced operative shock was inadmissible, as the condition of the patient immediately preceding the first collapse was perfectly satisfactory. An acute circulatory crisis seemed to offer the most reasonable explanation of death. Coronary thrombosis appeared unlikely, and some form of gross embolism as the cause of death was arrived at by a process of exclusion. Air embolism seemed a distinct possibility, as venous bleeding had occurred immediately before the collapse, although it was not severe and no sucking had been heard. On the other hand, the right shoulder had been slightly raised on a sand-bag, and under these circumstances there is usually a negative pressure in the axillary vein during inspiration.

Post-Mortem Examination

Death occurred at 4.45 p.m., and a post-mortem examination was begun next day at 10 a.m. The essential findings were as follows.

No evidence of putrefactive change was found. As air embolism was considered as a possible cause of death the front of the thoracic cage was very carefully removed. The heart was seen to be distended on the right side, and on elevating the apex with the fingers the coronary sinus and its tributary vessels were seen to contain large numbers of air bubbles. The thorax was then filled with water and the heart showed a marked tendency to float. The heart was depressed with the fingers so that it was completely immersed below the surface of the water, and the lateral margin of the right ventricle was stripped with scissors. An impressively large volume of gas rose to the surface. This must have almost completely filled

the right side of the heart, because very little blood escaped after opening the heart and only a small clot was present.

On further examination of the heart the foramen ovale was found to be patent but well guarded by valve action. The anterior cusp of the aortic valve was adherent to the right posterior cusp, and this may have slightly impaired the efficiency of the valve, but the defect was not a gross one. No marked pathological changes of the other valves were seen. The coronary arteries showed only minor atheromatous changes.

Discussion

Air embolism may involve the right side of the circulation, the left side, or both sides. In this case it seems that air entered the torn slightly elevated axillary vein and made its way to the right side of the heart, where it was found in large quantity. This was undoubtedly the cause of death. Post-mortem examination confirmed the presence of a minor lesion of the aortic valve which had been detected clinically fifteen years previously, and the condition of the heart may have been a contributory factor.

Opinions differ regarding the minimum volume of air that, by entering the circulation, may produce a fatal result. Richardson, Coles, and Hall (1937) examined the results of experiments carried out on dogs by Harkins and Harmon (1934) and, applying these results to man, came to the conclusion that the rather large amount of 480 c.cm. would be necessary to cause death. In the course of their own work on dogs, however, Richardson and his colleagues showed that several factors governed the amount of air necessary to kill their animals. Chief of these was the rate of entry of the air, but they also found that the general condition of the animal as evidenced by the systemic blood pressure played a great part in determining tolerance to intravenously injected air. Much less air was fatal to animals with low blood pressure than to those with a normal blood pressure. These investigators considered that such factors as trauma, pain, apprehension, loss of blood, etc. were also of paramount importance. Simpson (1942) claims that under certain circumstances even 10 to 15 c.cm. may cause a fatal outcome in human beings. Whitby and Britton (1946) accept his statement that while a surprisingly large volume of air can be tolerated by a healthy subject, no more than a few cubic centimetres may precipitate death in a patient gravely ill.

Although air embolism was suspected as the cause of death in our case, post-mortem examination was necessary to prove that this was correct. In some cases a hissing noise may be heard as air enters the vein, and in animals splashing and churning noises may be heard with the unaided ear. In human beings, however, such findings must be rare, and the cause of death may be unsuspected until revealed at necropsy. Evans and Murley (1945) report such a case, and state that necropsy prevented the death being written off as due to a complication of severe malaria. Auer and Krueger (1946) report a similar experience following operative procedures on the spinal cord and skull in a number of rabbits. These animals died more or less acutely, and death was at first attributed to "vascular shock." After careful necropsy death was ascribed to air embolism associated with fibrin formation in the right ventricle of the heart. There is no doubt that the diagnosis of air embolism must often be missed unless a post-mortem examination is carried out, and Simpson has suggested that the diagnosis of air embolism may be missed even at necropsy if not previously suspected.

Summary

A case of fatal air embolism during mastectomy is described. Diagnosis of air embolism may be missed unless a post-mortem

amination is made, and even then may, in view of the small volume of air sometimes involved, be overlooked unless previously suspected.

HYPERTROPHIC PYLORIC STENOSIS IN THE ADULT

BY

A. HOBSON, F.R.C.S.

Consulting Surgeon, Battersea General Hospital.
Surgeon, Nelson Hospital

Hypertrophic pyloric stenosis in the adult is a somewhat unusual condition but is perhaps not quite as rare as it is held to be. In four years I had two cases that showed one or two unusual features, and therefore put them on record. A full bibliography and a discussion of the condition appear in an article by Howard Wakefield (1944).

The condition appears much more often in men (80%). Most patients have persistent stomach trouble, mild in character, from birth onwards. This characteristic suggests that, aetiologically, the stenosis is a persistence of a milder congenital stenosis. The usual complaint is of bouts of vomiting or of a feeling of nausea after meals. Pain is absent or slight. Few, if any, develop gastric or duodenal ulceration. The cases are nearly always diagnosed as carcinoma ventriculi and operated upon as such. In fact, the consensus of opinion is that diagnosis of the condition before operation, or even at operation, is difficult if not impossible with safety to the patient. In other words, the condition must be treated as a carcinoma even if a strong suspicion is felt as to the correct diagnosis. A mass is rarely palpable before operation.

Radiography reveals an elongated pyloric canal devoid of peristalsis (Berk and Dunlap, 1944). Macroscopically, the muscular coat of the pylorus is much hypertrophied and the circular coat on section tends to present the appearance of a palisade. The thickening ends abruptly on the duodenal side but shades off into normal thickness towards the stomach. To the naked eye the resemblance to "leather-bottle" stomach is close. The maximum thickness of the hypertrophied muscle yet reported appears to be about 1/3 in. (0.8 cm.). Microscopically, chronic gastritis is shown. About 100 cases are on record, including 81 out of 60,000 gastric patients treated at the Mayo Clinic from 1927 to 1931.

The two cases here reported were both in females, and were unusual in the complete absence of any history of gastric upset until very shortly before operation. The x-ray picture in both cases was typical, and, except for the extraordinary thickness of the pylorus in the second case, the appearances at operation and pathologically were again typical. One of these patients, who was somewhat peculiar mentally and who was in the habit of consuming large quantities of raw rice and lentils (whether the cause of the disease or a consequence cannot be said), had a hyperchlorhydria, the other an achlorhydria. It has been noted

that the condition seems to occur in "aggressive and martial" types. Both these patients were quiet and somewhat subdued.

As I have had these two cases within such a comparatively short time, it is quite possible that milder degrees of hypertrophic pyloric stenosis are commoner in adults than is supposed and may be missed if not specially looked for. In cases of persistent gastric trouble, with some stenosis revealed on radiography and little or nothing found at operation, it would seem advisable to keep the condition in mind. Whether any less drastic treatment than partial gastrectomy would suffice to bring about a cure in the milder cases it is difficult to say, but it would seem well worth while to try the effect of simple gastrojejunostomy or a plastic operation on the pylorus, provided the diagnosis was clear enough at the time of operation.

Case 1

Mrs. B. E. V., aged 55, had had an epigastric pain radiating to the left side of the abdomen for two months; vomiting for three to four weeks, chiefly in bed at night; a feeling of fullness later and of a heavy weight across the upper part of the abdomen; and a loss of appetite for more than a year. There had been much loss of weight during the last few months (this is the patient who had a passion for raw rice). She had been in hospital two months previously with a mild chronic nephritis.

Examination showed the patient to be somewhat thin; there was a systolic murmur in all areas, and tenderness in the epigastric region. No mass was felt. Cystocele was present; she had to get up three times a night to pass water. Radiographs showed a persistent filling defect of the antrum, with an irregular outline typical of carcinoma ventriculi. There was a considerable gastric residue at six hours. A test meal revealed hyperacidity and no blood. A blood count showed: red cells, 4,000,000; Hb, 74; colour index, 0.9.

At operation the pyloric end of the stomach was found to be much thickened but soft. A partial gastrectomy was performed, with a posterior gastrojejunostomy after dividing the ligament of Treitz. On the day after operation there was a little basal collapse; this soon cleared up, and the patient progressed very well. When readmitted to hospital two months after her operation for a colporrhaphy she was in very good health and underwent the operation without untoward effects. One year later she was still in very good condition, with no gastric symptoms, good appetite, and a more normal weight.

On section of the pylorus the pathologist reported: "Chronic gastritis with oedema of slightly fibrotic hypertrophied muscle of pyloric part of stomach." Naked-eye inspection of the pyloric end of the stomach revealed a great thickening of the muscular coats, which measured quite 1/3 in. (0.8 cm.) across. The muscle showed a typical palisade appearance. The hypertrophy stopped short at the duodenum but gradually shaded off into normal stomach wall at about the middle of the lesser curvature.

In view of the connexion between pyloric stenosis and uraemia it is interesting to note that two months before gastrectomy her blood urea was 94.28 mg. per 100 ml.; at the time of operation it was 40.5 mg., and three months later it was only 17.15 mg.

Case 2

Mrs. F. A., aged 54, complained of pain in the lower chest for six weeks, with a loss of 12 lb. (5.4 kg.) in the last four months. She felt sick all the time, bringing up water, and occasionally food. Pain came on a quarter of an hour after food and lasted a few minutes. There was a tendency to feel faint. She started to get a little indigestion about 18 months before. Her appetite was poor.

On examination a definite mass could be felt at the pyloric end of the stomach.

Radiography (see illustration) showed a filling defect, giving a smooth and non-contractile outline to the pyloric end of the stomach extending from the pylorus to half-way along the lesser

curvature. The radiologist reported: "Findings consistent with an extensive pyloric carcinoma." A test meal showed complete achlorhydria with a low total acidity. Occult blood, negative; blood urea, 50 mg. per 100 ml.

Tracing of radiograph of Case 2. X=filling defect.

At operation the pyloric end of the stomach was found to be thickened and the transverse mesocolon was adherent to the stomach, the adhesions involving the middle colic artery. A partial gastrectomy with a posterior anastomosis was performed with some difficulty. The patient made an uninterrupted recovery.

The following is a report on the pathological findings, naked eye and microscopical, by Dr. Stanley F. Marshall: "There is marked hypertrophy of the outer muscular coat, which is visible macroscopically on the slide. Microscopically, large bundles of smooth muscle fibres are seen—presumably the longitudinal coat beneath the serous coat and occupying about two-thirds of the thickness of the wall, which is about

1/2 in. (1.25 cm.) thick at its widest. Lymphocytic aggregations are scattered among and superficial to these hypertrophied muscle fibres. Numerous granulation and inflammatory cells are seen in the submucous coat. Three lymph glands in the vicinity show moderate inflammatory reticulosis only. No evidence of malignancy was seen." Naked-eye examination showed typical palisading of the muscular coat, which when first removed from the patient was nearly 3/4 in. (1.9 cm.) thick.

Summary

Two cases of hypertrophic pyloric stenosis in the adult are reported. Both show an absence of the usual lifelong history of gastric discomfort. One had a remarkably thick muscular coat and presented a palpable mass before operation.

The view is expressed that mild degrees of the condition may be relatively common, and the suggestion made that if the difficulties of accurate diagnosis can be overcome some less drastic treatment than partial gastrectomy may be possible.

Under the new national insurance scheme, which comes into full operation on July 5, 1948, a single contribution card will be issued for each insured person. The contribution will be paid by affixing a single stamp to this card. The standard card, which will be current for 52 weeks, will consist of two leaves, but some of the cards issued at the outset of the new scheme will cover a period of 74 weeks and will consist of three leaves.

CONGENITAL HYPERTROPHIC PYLORIC STENOSIS

REPORT OF FOUR CASES IN BROTHERS

BY

A. A. H. GAILEY, M.D., D.C.H.

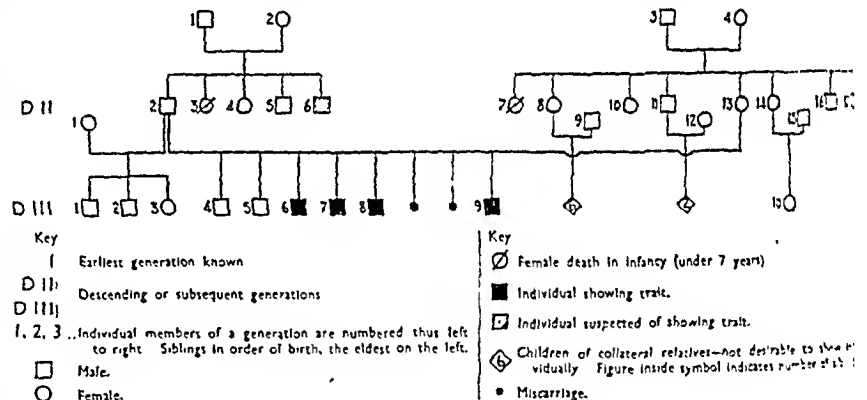

Medical Registrar at the Belfast Hospital for Sick Children.

Several authors have reported two or three siblings with congenital hypertrophic pyloric stenosis, but in search of the literature I have been able to find only one instance.

Clinical Features of the Cases

Clinical Features	Peter D III/6	John D III/7	Brendon D III/8	Patrick D III/9
Date of birth	29/3/39	9/6/41	30/7/43	6/2/44
Gestation, labour, delivery	Normal	Normal	Normal	Normal
Sex	Male	Male	Male	Male
Position in family	3rd	4th	5th	6th
Birth weight	9 lb. 8 oz. (4.3 kg.)	6 lb. 10 oz. (3 kg.)	9 lb. 10 oz. (4.08 kg.)	(4.51 kg.)
Foetal abnormalities	None	None	None	None
Feeding prior to symptoms	Breast	Breast	Breast	Breast
Age at onset of symptoms	59 days	7 days	15 days	10 days
Projectile vomiting	Yes	Yes	Yes	Yes
Visible peristalsis	Yes	Yes	No note	Yes
Pyloric tumour palpable	Doubtful	Doubtful	No note	No
Bowel action	Constipated	Constipated	Normal	Constipated
Age on admission	78 days	18 days	27 days	31 days
Dehydration before operation	Yes	No	Yes	No
Age at operation	80 days	19 days	28 days	33 days
Age on discharge	85 days	21 days	31 days	42 days

of this condition being discovered in four members of the same family—a family reported by Finkelstein, quoted by Sauer (1924). Each of the four cases here reported show

the classical clinical picture. They were the children of the father's second marriage, and were preceded by two sisters, one stepsister, and two brothers, all of whom were normal. The clinical features are outlined in the table.

In each of these cases Rammstedt's operation was successfully performed and convalescence was uneventful. The three older boys have "never looked behind them," and have developed into normal healthy boys. The youngest (Patrick), more than two months after his operation, is thriving and putting on weight regularly.

An attempt was made to gain enough information to prepare a family tree, but the parents (Mr. and Mrs. C.) were unable to remember any details before their own generation, and as the grandparents are dead and the rest of the family scattered it was impossible to build up a complete picture of the family. However, the accompanying genealogical table shows the details that were obtained of the two generations. The symbols used are those recommended by the Eugenics Society.

In the generation D II there are three interesting members. D II/3 and D II/7 were sisters of Mr. C. and Mrs. C. respectively, and both died at the age of 2 years, the cause of death and the nature of the illness being unknown. D II/6, a brother of Mr. C., was reported to

ve been ill from shortly after birth with severe "gushing" and persistent vomiting, so that both breast-feeding and bottle-feeding were impossible, and he was able to keep anything down only by receiving very small feeds from a syringe. After a very stormy illness, during which there were times when his life was despaired of, he started to make a recovery about the age of 1 year and is now reported to be a very healthy man in Canada. This boy's illness was considered by his mother, I/2, to have been exactly the same as that of her grandson, Peter D III/6, the first case of this report. In view of this story I have ventured to record him as a suspected case of congenital hypertrophic pyloric stenosis, and have represented him by a shaded square.

While there is still disagreement on the aetiology of congenital hypertrophic pyloric stenosis, most authorities seem to agree that the condition is congenital, that the hypertrophy is primary, and that the spasm, to which the initial picture is probably due, is secondary to the hypertrophy. In this family the condition appears to have been transmitted as a Mendelian recessive character.

I am grateful to Dr. F. M. B. Allen, under whose care they were, and to Mr. H. P. Hall and Mr. J. S. Loughridge, who performed the operations, for permission to publish notes of these cases.

Medical Memoranda

A Case of Epidermolysis Bullosa

The following case is considered to be an example of epidermolysis bullosa and to belong to a rare variety which develops in adult life. It is stated in the literature that some cases resolve spontaneously; it is therefore notable that in the present case relapse occurred two years after spontaneous recovery from the disease.

CASE HISTORY

A naval telegraphist aged 19 was sent to hospital complaining of blisters forming on his hands. It appeared that for about two years he had been liable to lose large areas of skin if he slipped and bruised himself. The skin "slid off." Confirmation of this was supplied by the numerous discoloured areas in places where trauma was readily sustained, but there was no scarring anywhere. About eighteen months previously he had a similar attack involving the hands; this cleared up quite quickly, and recently he had been under treatment with impetigo of the face, which was also of a vesicular nature and which cleared with penicillin cream. There was no other relevant previous history or any relevant family history.

On examination many flaccid and unilocular blisters varying in size from 3 by 2 in. (7.5 by 5 cm.) to minute vesicles were seen arising off normal skin and unattended by itching, soreness, or malaise (see photograph). The skin enclosing the blisters was noticeably tough. Burst blisters dried up and did not form crusts, nor did the blister contents tend to become purulent. The bullae were at the time confined to the hands, but there were discoloured marks of old lesions on the elbows and a few on the shins and knees. His nails and teeth were normal. Examination of other systems revealed no abnormalities. The fundi were normal, and there was no hyperhidrosis. A blood count showed: R.B.C., 4,960,000 per c.mm.; haemoglobin, 96% (Sahli); colour index, 0.97; W.B.C., 9,600 per c.mm. (polymorphs, 37%; lymphocytes, 57%; monocytes, 3%; eosinophils, 3%). A further count seven days later gave a similar result. The Paul-Bunnell reaction was positive to 1 in 16 only. A radiograph of the chest revealed nothing abnormal. The urine was normal; there were no bromides or iodine, and no darkening on standing. The Kahn test was negative. The blister fluid was sterile on culture; cytology: 3% polymorphs, 96% lymphocytes, and 1% eosinophils.

A small area of skin on the back of the hand was rubbed firmly and a blister formed in 18 hours.

COMMENT

Differential Diagnosis.—Apart from many easily excluded bullous diseases, there are a few which can give trouble in differentiation. These, with the main points of difference, are: (1) *Pemphigus*:—The health deteriorates, and the patient with well-developed pemphigus is usually an ill person; widespread and not confined to traumatic areas. (2) *Impetigo bullosum*:—Typical lesions elsewhere and presence of infection. (3) *Iodism* and *bromism*:—Test urine. (4) *Syphilis*:—History and positive

The patient's hand on admission. (Photograph by courtesy of the Fleet Photographic Officer, Malta.)

Kahn reaction. (5) *Syringomyelia*:—No other confirmatory signs. (6) *Dermatitis herpetiformis*:—Polymorphism and itching.

Treatment.—Arsenic in various forms is recommended, but it has had no effect in this case. Ultra-violet light is also said to be of use, but, in the main, treatment must be symptomatic until the cause of this disorder is discovered. It is perhaps notable that the first attack in this case subsided after six weeks without any other than protective treatment.

I am indebted to Surgeon Rear-Admiral Brownfield for permission to publish this case.

B. S. LEWIS, D.S.C., M.R.C.S., L.R.C.P.,
Surgeon Commander, Royal Navy.

Speaking at the annual general meeting of the Industrial Welfare Society on Nov. 25, 1947, Lord Trent said that there had been a considerable increase in membership. Requests for information about personnel policy poured into headquarters all the year round, and more than 2,500 such inquiries had been dealt with. During the year some 715 firms had been visited. Specialist advice was given on such subjects as education and training schemes, canteen planning, joint consultative machinery, the organization of personnel departments, and many others.

DERMATOLOGY

H. HALDIN-DAVIS.

SEROLOGY

G. S. WILSON.

Our colleagues in the U.S.A. are tackling with characteristic energy and thoroughness the national aspect of a world-wide problem—namely, how to provide a complete medical service for all who need it. The New York Academy of Medicine set up a committee whose reference is "to review the nature, quality, and direction of the economic and social changes that are taking place; to define how these are likely to affect medicine; and to determine how the best elements in medicine may be preserved embodied

It was obvious that in recent years there has been in the U.S.A. a great extension of State and Local activity in this field and that one of the first requirements of the committee was to know how far and in what ways this tendency had evolved. This book, fathered by the Government, Dr. Lund and written by Dr. Bernhard Stern, formerly at the University of Columbia, seems to supply the need very adequately.

Dr. Stern in a preface says that practically all government provision of medical care stems from the original local commitment to responsibility for the care of the sick poor. Dr. Stern goes on to trace it from the ground upwards. Many of the problems dealt with are familiar to us, but we have been impressed by one of the toughest which is inherent in the federal system of government in an immense country. The federal States are shown to be jealous of Federal encroachments on their rights, and in their turn find similar jealousies in other community authorities. This attitude has led to great differences in the amount and quality of medical services provided communally. Though Dr. Stern does not directly say so, it seems probable that many of them will be met by increasing central financial grants, with, no doubt, increasing central direction. The book is very fully documented.

ALFRED COX.

VIENNESE TWILIGHT

The Art of Healing. By Bernard Aschner, M.D. (Pp. 336, 2s. 6d.) London: Research Books, Ltd., 1947.

This book is written by a gynaecologist who taught "medicine" at the University of Vienna from 1918 to 1938 and who is said to have written several medical textbooks in explanation of the methods used by himself in the treatment of disease. It is now dignified by the title of "Constitutional Therapy." The methods include bleeding, cupping, and leeches as a means of eliminating various toxins (menstruation is highly commended for the same reason, which makes the male patient feel for the first time that he may have missed something after all, emesis as a treatment for schizophrenia, and the employment of many drugs long since excluded from orthodox medicine by reason of their pharmacological inertness. This system of "Constitutional Therapy" should not be confused with that described in the excellent book by Julius Bauer, another physician from Vienna, entitled *Constitution and Diagnosis*, a medical philosophy of a very different order.

The author supports his claims by a series of dogmatic statements whose refutation would occupy a regiment of research workers for a lifetime. He quotes, with disapproval, the retort of a scientist to whom he was explaining the importance of the colour of hair, eyes, and skin in assessing constitution: "You are quite right. Unfortunately I still have another twenty years of cranial measurement to do, and then perhaps I shall find a cure for the problem of complexion." Dr. Aschner has preferred what Alroth Wright used to call the *salus empiricus* and has no doubt already received his reward, but he cannot hope to succeed in his avowed aim "to re-establish fully the partially shattered confidence of the public in scientific medicine." British physicians see more clearly than the author the limitations of present-day therapy—its mechanism, its preoccupation with the end-results of disease processes, its failure to consider the whole man—but that does not mean that we wish to return with him to the mediæval mess of leeches, purges, emetics, and clysters from which we have just painfully emerged.

D. V. HUBBLE.

As Rhine and Carington have shown, it is possible to write dispassionately about extra-sensory perception, telepathy, precognition, and similar subjects. These workers and Dr. Soal have accumulated valuable experimental data under rigid laboratory conditions. It is a pity that Mr. G. N. M. Tyrrell has not found more space in *The Personality of Man: New Facts and their Significance* (Pelican Books, Harmondsworth, 1s.) to discuss work of this kind; he makes good the deficiency by an abundance of material of a more anecdotal and dramatic nature. His book is frankly polemic. He has a bone to pick with the scientific critics, whose attitude he attributes to "a quite primitive psychological foundation"; and he underestimates the force of their objections. It is to be feared that his aggressive partisanship will come between him and the inquiring reader.

[Review is not precluded by notice here of books recently received]

The Transactions of the Hunterian Society. Vol. V. Edited by Mr. A. E. Mortimer Woolf. (Pp. 119. No price.) London: Metropolis Press. 1946-7.

Includes Hunterian Oration on "Literary Surgeons," by Zachary Cope, a discussion on "Flatulence," opened by Geoffrey Evans, and a discussion on "Sprains and Strains," opened by Sir R. Watson-Jones.

The Medical Annual, 1947. 65th Year. Edited by Sir Henry Tidy, K.B.E., M.A., M.D., F.R.C.P., and A. Rendle Short, M.D., B.S., B.Sc., F.R.C.S. (Pp. 441. 25s.) Bristol: John Wright and Sons, Ltd.; London: Simpkin Marshall (1941), Ltd.

Recent advances in medical and surgical treatment.

A Memory of Solferino. By J. Henry Dunant. (Pp. 64. 6s.) London: Cassell and Co., Ltd. 1947.

A short story of battle by the founder of the Red Cross

Gifford's Textbook of Ophthalmology. By Francis H. Adler, M.D. 4th ed. Illustrated. (Pp. 512. 30s.) London and Philadelphia: W. B. Saunders Company.

Intended particularly for the medical student and general physician.

Developmental Diagnosis. By Arnold Gesell, M.D., and Catharine S. Amatruda, M.D. 2nd ed. (Pp. 496. 32s. 6d.) London: Hamish Hamilton Medical Books. 1947.

An account of abnormalities of physical and mental development.

Some Lessons of War-time Psychiatry. By Kenneth Soddy, M.D., D.P.M. (Pp. 23. 1s.) London: National Association for Mental Health.

Makes suggestions about a psychiatric service in the light of experience gained during the war.

The Story of St. Thomas's, 1106-1947. By Charles Graves. (Pp. 72. 8s. 6d.) London: Adprint, Ltd. 1947.

A short illustrated history of the famous teaching hospital.

Johannes Fibiger. By Knud Secher. (Pp. 206. £1.) London: H. K. Lewis. 1947.

A biography stressing particularly Fibiger's contributions to cancer research. In English.

Lectures on the Liver and its Diseases. By H. P. Himsworth, M.D., F.R.C.P. (Pp. 204. 18s. 6d.) Oxford: Blackwell Scientific Publications. 1947.

An account of recent knowledge about the liver, its functions and disorders.

Hipertensión Arterial y Tiocianato de Potasio. By Alfredo Claudio Carrera. (Pp. 434. No price.) Buenos Aires: Estudio Clínico y Experimental. 1946.

A monograph on hypertension and its treatment by potassium thiocyanate.

The Internal Fixation of Fractures. By C. S. Venable, M.D., M.S., F.A.C.S., and W. G. Stuck, M.D., M.S., F.A.C.S. (Pp. 237. 30s.) Oxford: Blackwell Scientific Publications. 1947.

An account of the history and modern methods of fracture fixation by means of internal appliances.

A Hand-Book of Ocular Therapeutics. By the late Sanford R. Gifford, M.D., F.A.C.S. Revised by D. Vail, M.D., D.O., F.A.C.S. 4th ed. (Pp. 336. 25s.) London: Henry Kimpton. 1947.

A manual of therapeutics in ophthalmology. The chapter on disorders of the muscular apparatus has been removed.

London Children in War-time Oxford. By a Barnett House Study Group. (Pp. 113. 6s.) London: Geoffrey Cumberlege. 1947.

A survey of the effects of wartime evacuation on children.

The 1947 Year Book of General Therapeutics. Edited by Oscar W. Bethea, Ph.M., M.D., F.A.C.P. (Pp. 455. 21s.) London: H. K. Lewis.

A summarized account of recent advances.

Basic Mental Concepts. By Edward Glover, M.D. (Pp. 32. 3s. 6d.) London: Imago Publishing Co. 1947.

An account of the basic concepts of psycho-analysis.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JANUARY 17 1948

WHY BE FEARFUL?

The Representative Body last week said No with a determination. Some doctors were naturally anxious about the result of saying No. The fear of the paymaster was one of them—a fear, no doubt, that Mr. Bevan would mean in his estimate of the chances of successful opposition to the profession to his Health Service Act in the next few months.

But the power of the purse—or will have if the Act is passed—decide to enter his Service on July 5. But, at the Representative Meeting last week, we heard one thing to fear—"and that is that the profession does not know its own mind." It is for medical men to state the mind of the medical profession in answering the questions on the plebiscite sent out on Jan. 31. Opposition to the Act requires a sufficient majority which includes 13,000 practitioners votes No.

In its present form the Act is the first and irrevocable step towards a whole-time State Medical Service (not Health Service). If doctors are convinced that this is a step that they hold fast to their centuries-old detestation of State medicine—then the Noes will have it. The Representative Body have given the lead. It will abide by the decision of the majority as they vote.

Men and women must vote on the merits of the case. If they believe their case to be good and just, their duty is to vote accordingly. Montgomery knew it was not his army that would defeat our Army at El Alamein—not the numerical superiority of the enemy. He forbade his officers to use phrases such as "It's bound to come." His first duty was to eliminate fear and the use of fearful slogans. And he won his battle. If the plebiscite results in the necessary volume of Noes we shall win our case with the Minister of Health if we succeed in banishing fear and move forward with the strength of conviction.

What are the fears that men have? Doctors are not a class. They do not form a class whose money is inherited by heredity. They work hard—probably longer hours than any other section of the community. They are subject to great strain and stress. The love of their work makes them more devoted to their work than any other group of workers would be. They are taught and to be taught and to be taught and to be taught. In Britain this freedom of general practices and of the medical profession. This freedom is now being threatened. The medical man most fear is this freedom. The medical man most fear is this freedom.

Mr. Bevan thinks he has a trump card in offering compensation to those general practitioners who do not enter the Service on July 5. Is he right? The Association will advise general practitioners not to enter the Service only if the number who say No is sufficient to defeat Mr. Bevan. This number must be large enough on Jan. 31 and remain large enough until July 5. Faced by what will probably be overwhelming opposition Mr. Bevan will choose between postponing the appointed day or adhering to it. If he postpones it the compensation and other issues will also be postponed, and National Health Insurance will continue. If he does not postpone it he will be unable to operate his Service because he will not have the man-power. Again, he is defeated. He must in that case come to terms with the medical profession, terms which will have to be acceptable to those who have voted No. The strength of the profession will lie in the size of the majority against the Act.

The doctor who votes No may temporarily suffer because a doctor in the next street votes Yes. The B.M.A. has substantial funds at its disposal to tide him over this difficulty. In any case the Yes man is unlikely to be a superman, nor even, may it be said, a better doctor. A doctor gives his services and has a right to be paid for them. Mr. Bevan's Health Service is not an insurance scheme, as National Health Insurance is. The man between 18 and 65 who pays his social insurance contribution of 5s. a week is providing only 10d. a week to the Health Service. And nearly half the population of Britain will not ever be paying this.

Those who fear that some men may change their No into Yes between February and July may be assured by the knowledge that the B.M.A. will know exactly to what extent this is occurring even if it occurs at all. The B.M.A. will persist in opposition only if the necessary majority is maintained. If the Noes are in the sufficient majority medical men will be asked to form small security groups in each division. They will be asked to enter into bonds with one another, and thus keep firm their Noes.

Consultants and specialists have little or nothing to fear. They will not be able to sign contracts with hospitals, because such contracts will not be ready. In any event the hospitals cannot do without them. Those who sincerely believe that the Act in its present form is directed towards the establishment of State medicine are asked to sign No. Hospital residents—those temporarily in whole-time employment—are asked not to enter the Service as general practitioners or consultants but to carry on with their work.

Doctors have been criticized for being "emotional" over the present conflict. It was the strength of emotion that held this country firm between 1939-45. Emotion, if we are to believe modern psychology, is the driving force behind reason and action. Opposition to State medicine certainly has a basis in reason, but perhaps a much sounder basis in emotion. Five hundred years ago Medicine had to free itself from the dictatorship of authority—the authority of Galen. This freedom was won by men who thought fearlessly. To-day we are faced with that recurring historical phenomenon—the dictatorship of the State. We can defeat this in Medicine if we think and fight fearlessly, and we need not be ashamed of emotion if we avoid that perversion of emotion called hysteria.

STREPTOMYCIN IN TUBERCULOSIS

Streptomycin is so far the only antibiotic of many studied since the discovery of penicillin to take an assured place among existing chemotherapeutic agents. Experience of its use in this country is so far limited, although it is now a year since the Medical Research Council allocated supplies to a limited number of hospitals with the object of studying its effect both in certain forms of tuberculosis and in other infections specially susceptible to it. The scheme for the treatment of military and meningeal forms of tubercle is has now been extended by the Ministry of Health, and many such cases have been or are being treated, but it is too early to assess results in terms of ultimate prognosis. In the U.S.A., on the other hand, therapeutic studies were begun two years earlier and have since been extended on a scale which our present supplies do not permit. The accumulated experience of American workers is thus a valuable, and indeed almost our only, guide to the clinical use of streptomycin. A leading part in the study of the treatment of tuberculosis has been taken by W. H. Feldman and H. C. Hinshaw, of the Mayo Clinic, the former from the experimental and the latter from the clinical point of view. It is our privilege to publish to-day a paper in which they give a general account of this work and an assessment of its results. Their conclusions are the up-to-date outcome of extensive experience, and will command wide attention, even though some of the practical lessons cannot yet be put into effect.

There are two main facts about the acute forms of the disease which we are now treating ourselves. One is that in tuberculous meningitis and military tuberculosis early treatment brings about a remission in 50% of cases; the second that such remissions have been observed to last for over two years. On the other hand, if a recurrence takes place, and if the tubercle bacillus has acquired resistance to the drug, further treatment is useless. It will be interesting to have more details of American experience in the treatment of tuberculous meningitis to compare with the remarkable series described by R. Dôré and his colleagues in the *Journal* a few weeks ago.¹ Within the compass of a general survey it was naturally not possible to embody a discussion of the indications for streptomycin treatment in pulmonary form of the disease: these have been defined elsewhere. Further experience has confirmed the earlier conclusion that actively progressive disease is often at least temporarily arrested, with obvious and immediate benefit. Ulcerative lesions of the air passages, notably laryngitis but including similar lesions of the trachea and bronchi and of the pharynx and tongue, appear to respond well and regularly, and treatment is considered to be clearly indicated even though its object may be only palliative. Symptomatic relief can also be obtained in tuberculous enteritis, and here again administration is justified even without hope of effect on the ultimate prognosis. In "surgical" forms of tuberculosis it has also been found that the drug can play a valuable part. As might perhaps be expected by analogy with the action of penicillin, it is without any radical effect on established disease of bones and joints. Unlike penicillin, it is incapable of sterilizing large collections of pus; it has previously been pointed out that this is probably due

to the great diminution in activity of streptomycin in an acid medium. On the other hand, with the protection afforded by the drug, such collections can now be drained, a procedure which otherwise is usually inadvisable. As an aid to surgical treatment in general, and particularly radical thoracic surgery, streptomycin is likely to prove of great value. Like other forms of chemotherapy, it is seen at its best when combined with appropriate surgical treatment rather than when relied on alone.

There is another side to this picture which is less encouraging; indeed, if one looks to the ultimate future of streptomycin treatment it can encourage nothing but frank pessimism. The unexampled degree and rapidity of bacterial habituation to streptomycin were recently discussed in these columns;² unfortunately *Mycobacterium tuberculosis* is no exception, although its acquisition of resistance, like everything else it does, seems to proceed in a more leisurely fashion. It has been shown in connexion with other species, notably *H. influenzae*,³ that large bacterial populations contain a small minority of naturally resistant cells, the exclusive multiplication of which during exposure to streptomycin, whether *in vivo* or *in vitro*, is evidently the source of the resistant populations produced. It appears from the studies of Marjorie M. Pyle⁴ that this is also true of the tubercle bacillus. Her method was to make quantitative cultures of the sputum of patients before and during streptomycin treatment for pulmonary tuberculosis, using sealed plates of an egg medium containing 9 different concentrations of streptomycin, from 1 to 1,000 micrograms per ml. In 7 out of 8 cases a few colonies (representing one in many thousands of the numbers on normal medium) were obtained on media containing 5 or 10 micrograms per ml. before treatment began. During a course of treatment occupying several months there was in 5 of the cases a steady increase in the proportion of resistant organisms and in the degree of their resistance; in one case of which the findings are given in full there were innumerable colonies resistant to 1,000 micrograms per ml. after 12 weeks. In two patients no increase in the resistance of the organism was observed, and in one the increase was only slight. These observations show incidentally that estimations of sensitivity performed with cultures derived from a single colony are of very limited value; we are dealing here with a mixed population in which a wide range of degrees of sensitivity may be represented. But their main lesson is that in perhaps a majority of patients the drug has only a limited time in which to do what good it can: thereafter that strain of tubercle bacillus will be quite unaffected by it. Presumably its resistance will continue in a further host, and patients uncured by this treatment should consequently be looked upon as peculiarly dangerous sources of infection.

Much as we may learn from clinical experience in the U.S.A. there is ample scope for further study, particularly in relation to systems of dosage and the theory of streptomycin action. The tendency has been to reduce both the total dose and the number of daily doses given, a common practice now being to give only two daily. This policy is supported by Feldman's observations in guinea-pigs, when still longer intervals or even treatment during alternate weeks did not appear to impair therapeutic effect. The efficacy of such intermittent attack on the tubercle bacillus seems inconsistent with the idea of a predominantly bac-

² *Ibid.*, 1948, 1, 20.

³ *J. exp. Med.*, 1947, 85, 329, 607.

the maintenance of an adequate level in the blood and the continuous administration should produce better results. Even though penicillin is known to have a bactericidal as well as a bacteriostatic effect, great ingenuity is required in devising methods of obtaining a continuous effect from each dose, on the well-founded assumption that continuous action at the site of infection is superior to intermittent. If this principle is applicable to penicillin but inapplicable to streptomycin we have yet to find the reason for the difference. Evidently there is, and the possibilities of experimental study which may throw some light on it have not been exhausted. In the meantime the present system of administration need not be regarded as final, and users of streptomycin in this country have the opportunity of trying to better it. The suggestion by Debré of a week's intensive treatment followed by a smaller maintenance dose is rational and worthy of further study. Perhaps the most difficult problem of all is when to stop treatment; in view of the lasting effect obtained while the bacillus gains resistance, and of our exiguous supplies of the drug, one conclusion we might well make to this study is to observe the effects of a shorter course.

RICKETS IN PREMATURE BABIES

Immaturity at birth is the chief cause of death during the first month of life. According to the Registrar-General's *Annual Report of England and Wales for 1945* there were 1,146 deaths certified as due to premature birth out of 1,146 deaths ascribed to "diseases peculiar to infants of life". Sometimes the immature infant dies because it is functionally incapable of adjusting itself to the conditions of post-natal life, perhaps more often an accident to him such as birth injury, asphyxia, or infection.

The prospects of a premature baby's survival have improved considerably during the present century. It is now possible, with adequate co-operation between general practitioners, paediatricians, and administrative medical officers, and with the necessary financial resources, a viable life may be saved and guided to a normal childhood. The practical possibilities of this work will be apparent when it is recalled that about 45,000 to 50,000 premature babies are born each year in England and Wales. These infants are prone to anaemia, rickets and other nutritional disorders, infections, delayed intellectual and physical development, and abnormal psychological reactions. A recent paper by Gert v. Sydow¹ presents a study covering a period of six years of the part played by vitamin D and minerals in the development of rickets in premature babies. The most important practical aspects of his work are the ground the diagnosis of rickets and the part of human milk in its prevention. The report of the British Paediatric Association on the incidence of rickets has drawn attention to the difficulties of clinical and radiological diagnosis. Gert v. Sydow's study is especially valuable in correlation of the radiological findings with the state of the blood. A series of 236 premature babies, born between 1939 and 1944, were under 2,000 g. (approximately 4 lb.) at birth and compared with 292 normal full-term babies. The blood was examined on estimations of calcium, phosphorus, and alkaline phosphorus, calcium,

and total protein and radiological examinations of the left wrist, and the results were studied by careful statistical methods. Metaphyseal decalcification was the earliest radiological change observed in infants subsequently showing signs of rickets. It was noted in more than half the premature infants after the first month of life. Fringing and cortical spurs, seen in the first half of the second month, are the earliest of the definite radiological changes. Cupping, spreading, and periosteal proliferation, to which von Chiari and Malmberg² had previously drawn attention, were found only infrequently and were then coincident with or subsequent to calcification at the epiphyseal line, which v. Sydow regards as a sign of healing but not of health. The author makes no reference to symptoms or clinical signs and perhaps this should be taken to mean that there were none. The point is important and should be settled authoritatively.

The premature baby is in special need of vitamin D because its rate of growth is rapid, fat absorption from the intestinal tract is poor, and its calcium stores are low. Human milk, which has always occupied pride of place as the ideal food for all newly born babies, and especially for those born prematurely, is relatively poor in calcium, phosphorus, and protein when compared with cow's milk. It has been suggested therefore that human milk should not be given to immature babies unless supplemented by additional calcium, phosphorus, and vitamin D.³ To study this question v. Sydow divided the patients into groups which were offered (a) human milk without supplements; (b) human milk and large doses of vitamin D; (c) cow's milk alone; (d) cow's milk and large doses of vitamin D; and (e) human milk and various additional calcium and phosphorus preparations. The following conclusions were drawn: human milk may not provide the premature infant with enough phosphorus, though it gives a fairly adequate supply of calcium; the calcium will be insufficiently absorbed unless vitamin D is also given. When cow's milk is used enough phosphorus but not enough calcium will be absorbed unless vitamin D is given.

TRAUMATIC AMNESIA

Transient loss of consciousness without physical after-effects is the common result of a head injury. The recovery of consciousness does not necessarily mean the full return of all cerebral functions. In the acute phase the cerebral paralysis involves motor, sensory, reflex, and mental functions. As is usual in the nervous system, recovery begins with the simplest mechanisms. Memory is the last function to return, and the total duration of the lapse of memory from the time of the injury—the period of post-traumatic amnesia—was regarded by Russell⁴ as a measure of the severity of the injury. If the head injury is more than trivial it is not uncommon for recollection of the moment of the impact to be obliterated, but this retrograde amnesia rarely extends appreciably into the past life of the individual. Ritchie Russell and Nathan⁵ have shown that the length of the phase of post-traumatic amnesia may indicate not only the severity of the immediate brain damage but also the future efficiency of the individual. This cerebral damage, which is entirely reversible with complete recovery in the mild cases and partial recovery in more severe cases, is not structural. In their work on experimental concussion Denny-Brown and Russell⁶ found no histological changes. They felt that the term "cerebral concussion" should be reserved for this immediate functional paralysis of the neurones. The neuronal damage is attributed to a general shake-up of the brain inside the skull produced by a change

¹ *Brain*, 1932, 55, 549.

³ *Lancet*, 1944, 1, 271.

...had any effect on the course of the disease. It is performed before or after the onset of the disease. Have recently been expressed the opinion that the relation of chorea to acute rheumatism he has followed the course of the disease in children and has found no significant difference from the course of the disease in children. He found that chorea must be regarded as a complication of rheumatic fever.

The incidence and severity of acute rheumatism have declined during the last 40 years. It is apt to attribute to the general rise in the incidence of the disease in Sweden, on the other hand, the change in the incidence of the disease in 1922 to 1931, though he did note a significant change during that period. While admitting that this may be due to an alteration of the "genus" of the disease, he considers that the real cause is to be found in the more efficient treatment as a result of earlier diagnosis and longer rest in bed and care. Thus, while in Sweden the natural history of acute rheumatism is broadly similar to that in Britain and the United States, there are interesting differences of detail which may be explained similarly in different countries with different climatic and social conditions.

NEEDLE BIOPSY

In order to obtain pathological material for histological examination, the means short of open operation is a needle biopsy, and established techniques are already available. From the puncture of the bone-marrow, the liver, and the spleen, Martin and E. B. Ellis¹ applied a technique to the biopsy of tumours, and other organs. They have reported favourably on their method. Ellis has now performed some hundreds of needle biopsies, and has obtained approximately the same results in tumours of glands, bones, and abdominal viscera. He uses the term "needle biopsy" to describe the insertion of a needle into a tumour, and the withdrawal of neoplastic material. "Drill biopsy" is an elaboration of the needle biopsy, a cannula being driven into the tumour by the use of a dentist's drill. This affords more delicate biopsy than needle puncture.

A correct diagnosis is necessary before starting treatment, and particularly the non-operative treatment, and there need no longer be any fear that the biopsy of a tumour hastens its spread.¹²⁻¹⁴ The biopsy of the neurofibroma are perhaps the only cases which have been clearly shown to become more malignant after partial surgical removal; to these may be added the mixed tumour of the parotid, which at present is only, if it does not undergo malignant change, a complete ablation. While the dangers of biopsy have been exaggerated in the past, there are certain cases in which they are probably greater with aspiration than with needle biopsy. Aspiration does not threaten the patient (Ellis reports only four cases in his series), but inadequacy of material may lead to faulty histological diagnosis. This is particularly true of bone sarcoma, whose variegated histology may include within a single tumour a range of mesoblastic tissue from virtually normal bone to highly anaplastic sarcoma; even open biopsy may secure from an undoubtedly malignant tumour only benign tissue.

The clinician's duty to the pathologist is to obtain at biopsy the largest possible amount of representative tissue, and this duty cannot always be discharged by an aspiration technique. It is seldom that open biopsy cannot be undertaken safely. Possibly the only clear indication for "aspiration biopsy" is in the case of a tumour so superficial, especially in the neck, that an open wound would offer a prospect of external fungation.

AMNIOTIC GRAFTS FOR BURNS OF THE EYE

Sorsby and others¹ recently described the results of treating burns of the eye by the application of amniotic-membrane grafts, and in 1946 Sorsby and Symons² published an account of their technique. The results indicate that it is a valuable method of treatment in suitable cases. Sterile, fat-free, dry amniotic membrane is used. Amnioplastin, as it is called, is supplied by the London Hospital in 1-in. (2.54-cm.) squares consisting of four layers of membrane. This is a convenient size to use if upper and lower parts of the conjunctiva are damaged, while it may be folded to half that size if only the lower part is to be treated. Conjunctival tissue is not removed, and the operation is carried out under local analgesia after preliminary treatment of the eye with penicillin drops. The dry membrane is secured by No. 0 silk sutures—inserted through each corner—and attached to the bulbar conjunctiva so as to separate it from the palpebral conjunctiva. Not more of the cornea should be covered than is necessary, and the graft is trimmed accordingly. Both eyes are bandaged for 48 hours, by which time the graft is clear and hardly visible. The sutures are removed on the third or fourth day, when the graft will have disappeared by absorption.

This simple operative procedure has been found of great benefit in limiting the after-effects of burns of the eye, especially if applied the same day as the accident, but it is also of value if used days later. It is indicated particularly in burns of the second degree. Burns of the first degree can be treated satisfactorily in other ways, and burns of the third degree—with necrosis or blackening of the conjunctiva—are better treated by excising necrosed tissue and replacing it by mucous-membrane grafts, as described by Denig and Siegel. In many cases treated by amniotic-membrane grafts the red and roughened conjunctiva became of nearly normal colour and smoothness in 48 hours, without any ulceration, as shown by absence of staining with fluorescein drops, and there was less tendency to complications affecting the cornea. In some instances where in the course of recovery from a burn there was a tendency for adhesions to form between the eye and the eyelid, the application of an amniotic membrane graft eliminated this tendency, and the result was evident in 48 hours.

Details of 30 cases are given and 28 in a previous publication referred to. Lime, sodium hydroxide, ammonia, and acids were among the substances causing the burns, which in a few cases involved the whole eye and in most cases the lower half of the eye. The results show that good vision (6/6 to 6/12) was maintained in nearly all the cases, and the description of individual cases makes it clear that this method of treating second-degree burns of the eye can produce remarkable improvement of the damaged conjunctiva in 48 hours.

THE MINISTER'S REPLY EXAMINED

A POINT-BY-POINT COMMENTARY

The General of the British Medical Association has examined in detail the Minister of Health's reply to the Negotiating Committee's case. We print its analysis below.

"The task now before the profession is to strip the proposals from the essentials, to distinguish between the shadow and substance."—From the Statement by the B.M.A. Council, Dec. 18, 1947.

What does the National Health Service Act of 1946 actually say? What is the gloss which the Minister's statement puts upon the Act? The profession is advised to distinguish carefully between the two.

No Compulsion to Join?

The Minister prefixes his reply to the representations of the Negotiating Committee with some general comments couched in private law if including language and "addressed to the individual doctor," possibly in the hope of separating the individual members of the profession from those who represent them. "The doctor," he assures the profession, "can participate in the scheme or not, just as he thinks fit. There is no compulsion to join." Yet, once a free medical service available to the whole community is operating, only by State payment can the great majority of general practitioners hope to live. But there is no compulsion to join. One can stay out and starve! The Minister adds that the doctor can participate "partly so and partly not," whereas the actual choice before the doctor is to join—and to give up the ownership of his goodwill and take a basic salary—or not to join and to be unable to accept a single public patient.

Will the Doctor be a Civil Servant?

"The word 'service,'" the Minister adds, "is perhaps a misnomer," having himself included the word in the description of his Act. "The doctor is not under orders," he says, though perhaps he should have said "not yet under orders." "The doctor is not employed," the Minister continues, whereas the Oxford Dictionary defines "employ" as "to use the service of." "He is not a Civil Servant," the Minister adds. Worse—he will be under the administrative control of the Civil Servant, medical and lay. Nor will he be a whole-time officer; he will be a part-time salaried officer; and the size of the salary element of his remuneration can be changed at any time by the Minister by regulation.

Then the Minister passes, with some alacrity, to the subject of remuneration. If a doctor takes on 4,000 potential patients under this scheme his gross income from "public funds," the Minister states, would be £3,300. How many doctors will have 4,000 persons on their lists? Each doctor can answer this for himself by dividing the population of his area by the number of general practitioners practising there. To-day the general maximum for insured persons is 2,500, and the average number on doctors' lists is about 1,000. It may be expected that under the new Service the average number of persons on a doctor's list will be just over 2,000. This average will decrease as the number of general practitioners increases. Remuneration in this case will be about £1,816. This is, perhaps, a better illustration of what the remuneration is likely to be. Deducting only 33½% for practice expenses, these figures become £2,200 for a maximum list and about £1,200 for an average list.

How Much Work Will it Mean?

The burden of a full list will be very considerable. The effect of introducing a free-at-the-time service is of course an increase in the number of items of service. National Health Insurance trebled the number of items of service. If the annual rate of items of service per person at risk remains as low as the present figure for insured persons, a list of 4,000 persons will need more than 20,000 items of service a year. This means, allowing a fortnight's holiday, just over 400 items of service

a week. At a six-day week this means about 70 items of service a day. Of course these will not be evenly distributed over the year. It will probably mean over 100 items a day for twenty weeks of the year and between 60 and 70 items a day for thirty weeks.

"In addition," the Minister goes on, "he may have private fees from other patients; other public or private paid appointments; additional fees for undertaking maternity work; mileage allowances, allowances for training assistants, and other extras." What he does not say is that the post of district medical officer will disappear; the post of public vaccinator will go; and the posts of Post Office medical officer and police surgeon will probably undergo contraction and eventual disappearance. Nor does the Minister mention that mileage allowances are no more than payments for travelling expenses and time spent—the greater the mileage allowance the smaller the doctor's list; that for those who undertake midwifery under the Service it will be well-nigh impossible to take on a full list; that in most areas private practice will be virtually non-existent. Yet the Minister says quite hopefully that in addition to the remuneration for a full list there will be remuneration from those other sources! "'O come into my parlour,' said the spider to the fly!"

In his section on "distribution" the Minister assures the profession that consent will be refused only in those few areas where there is clearly no need for additional public practice. If so, why create an administrative mountain to bring forth an obedient mouse? If the areas are so few, then why is he proposing a vast scheme of licensing of all incoming doctors before they can practise in the public service anywhere? "No doctor can be directed," the Minister says. But any doctor can be prevented from entering the public service in any area.

No Attempt to Justify the Basic Salary

A remarkable feature of this preliminary piece of Ministerial "public relations" is that there is not a word in it to justify the decision to make a basic salary an element in the remuneration of every general practitioner. First the basic salary was to be large; then it was to be small; then the Minister said that it was something "he had had in mind," implying that it was no longer "in mind." Now it is clear what he has had "in mind" throughout. Of course, a good case can be made out for a guaranteed minimum for a young practitioner in certain circumstances, as for the payment of additional inducements in specially difficult areas. But for the universal basic salary no arguments whatever are put forward. It is not surprising that the profession regards it as the first step to a State salaried service.

Some of these preliminary paragraphs are too good to be true, too rosy to be even plausible. Beneath all the Ministerial varnish the Act still stands, and in proceeding to examine the Minister's memorandum his assurances must be related to the Act as it is now worded. If there is one thing that is plain it is the Minister's blank refusal to amend the Act in any shape or form.

THE MINISTER'S STATEMENT AND THE ASSOCIATION'S COMMENTS

Points from the Minister's statement (in *italics*) are given below with the Association's comments.

The Minister states that he has never excluded—and does not now exclude—the possibility of amending legislation being found desirable. The discussions have not convinced him of any sufficient reason to go to Parliament now (Para. 3).

For nearly a year discussions have been proceeding on principle and detail, yet the Minister remains unconvinced that there is the slightest case for amending the Act in any particular or any detail. What he alleges will be easy for him to do, once the profession is in the Service, he cannot or will not do now.

The Minister finds no conflict between the seven general principles of the profession and the Act (Para. 5).

Let us examine the Act in relation to just two of the principles.

Principle 1: The medical profession is, in the public interest, opposed to any form of service which leads

the profession as a whole be-
cause of the interests of the State or local

general practitioners receiving part-
of the funds of the State. He can at any
time convert the proportion of remuneration
which he receives, convert it entirely into
a salary, if there is no conflict.

He should, like other workers, be free
to choose the form, place, and type of work they prefer
in any other direction.

General practitioners will not be free to choose
their work. They must first get permission from a
committee—even sons and daughters who desire
to follow in practice!

Distribution

It is difficult to justify the machinery
of the Medical Practices Committee. *He says that no doctor should have the right
to do remunerated work, implying throughout
that the level is one of public finance.*

General practitioners are remunerated by capitation fee, the individual
fee paid only in so far as the people of the area
are concerned. His success or failure would be
in the hands of the people. The Government's total commit-
ment to the service, and the choice of patients would
be the distribution of the public remuneration.

The Minister argues that the essence of the difference
between general practitioners are concerned is just that they
are paid by public funds, instead of by private fee. Now
because the doctor is paid by public funds he
must be free to practice. One begins to see a
universal basic salary. The Minister insists on
a basic salary, where it is unnecessary and then argues that
if you give a basic salary to everyone, then everyone
must obtain permission before entering an area for
practice.

He says that the Medical Practices Committee
is not to be taken to be efficient, saying
that it is a committee which will keep itself informed
of the public practice or establishments.

He says that even general practitioner who seeks
to practice in any area must first get permission
from the Medical Practices Committee, in every case
of the doctor is needed. The idea that com-
mittees and I think even the Minister with the object
of the committee remain ignorant of the whole
of the practice in every part of the country is
absurd.

He refers to the claim of a doctor to be an
owner of a practice, but says that the lack of acquaintance with the law
of the doctor is a mistake, and is representative
of the whole of the profession. This can be a "right" to
be appointed to a practice? When
the doctor becomes entitled to a very modest
remuneration in the practice and its maintenance ends.
He says that to prove that a system of universal license
is the only way to deal with what he now admits are a few
"bad doctors."

He says that extra inducement, coupled with the almost
total control of the Minister under Section 43 of the
Act, provides the Minister with
the means to deal with the situation.

He says that a doctor's area of practice, the
idea of a boundary line to stop
the Medical Practices Committee seem to think
that the Committee will be asked to make
a decision on the carrying on
of the practice in any part of the area.

He says that the Act "The Medical Prac-
tices Committee" will be asked to make
a decision on the carrying on
of the practice in any part of the area.

concerned is already adequate . . . the Committee may grant
an application subject to conditions *excluding the provision
of general medical services* by the applicant in such part or
parts of the area of the Executive Council as the Committee
may specify."

It will be the duty of the Medical Practices Committee to
carry out the Act, not the Minister's reply.

Ownership of Goodwill

The Minister has a closed mind on the subject of the pur-
chase by the State of the goodwill of the general practices of
those who enter the Service.

Existing Partnership Agreements

Here lies the acid test of the Minister's intentions on the
subject of amendment. Under Section 35 (4) of the Act there
are described three kinds of transaction which are deemed to
involve sale and purchase of goodwill and so to be illegal. The
first two refer to circumstances in which something is paid by
one partner to another for considerations other than work
done; the third where a partner receives more than his services
are worth. There then follows a so-called proviso which ex-
cludes certain transactions from the definition. The Minister
says that this proviso excludes *all* existing partnership agree-
ments so that they remain in full operation after the appointed
day. Our legal advisers say that the proviso excludes only
some partnership agreements—those where a partner is paid
more than the value of the services he renders.

Certainly Mr. Key, then Parliamentary Secretary to the
Ministry of Health, did not know what the proviso meant, for
all he said in moving its addition was as follows: "This
Amendment applies to assistant agreements. It is the same
principle as that applying to partnerships."

At first sight this might seem to be a mere legal quibble. But
our legal advisers regard the matter as one of great importance,
and Sir Cyril Radcliffe, K.C., and Mr. J. H. Stamp, having had
long experience in the interpreting of legislation, are not men
to use words lightly. They write as follows: "If Sections 35
and 36 are allowed to become operative without amendment
the profession and the Ministry alike will labour under em-
barrassing uncertainty on matters of great importance until the
debatable matters have been finally adjudicated upon, and in
the meantime steps may have been taken on the footing of a
construction which is ultimately found erroneous with unfor-
tunate consequences to all concerned. In our opinion it would
involve a real hardship to the practitioners concerned if they
were required to submit to such uncertainty when it has been
clearly foreseen and can be removed by an amending Act."

The Minister makes no attempt to refute the arguments put
forward by our legal advisers, merely stating that if he is found
to be wrong after the appointed day he will introduce legislation
to make his interpretation the right one.

He expects the members of partnerships to decide whether
or not to enter the Service without knowing whether in fact
their rights and obligations in their partnership deeds are nullified
by the Act. He leaves the whole position vague and ambiguous.
Soon a dispute will arise and it will be left to individual prac-
titioners to incur the expense of taking the case to the House of
Lords. If the Minister's interpretation is found to be wrong
and he, or his successor, carries out his promise of introducing
amending legislation, the position will be clarified for the
future, but nothing can be done to rectify the steps partners
have already taken in fulfilment of their agreements.

Such ambiguity having been demonstrated, surely the pro-
fession is entitled to have it removed before individuals are
called upon to decide whether or not to enter the Service.

The position is even worse, for our legal advisers give as
their opinion that *the Minister's own interpretation is incon-
sistent with the Act*. For example, the Act requires him to pay
interest annually on the compensation due to individuals and,
for reasons Counsel give in full in their opinion, the Minister
will be unable to carry out this requirement. The Minister
replies by claiming that his solution is equitable. But the
Negotiating Committee raised the point not as one of *equity* but
as one of *law*.

Again, the Minister's own interpretation means that where
a practitioner in the Service is in partnership with a practitioner

not in the Service the former may be called upon—under the partnership agreement—to purchase a private practice in respect of which no compensation is provided under the Act; the latter may be called upon to buy a public practice the income of which he cannot receive without joining the Service, so sacrificing the capital value of his own share and the one he has led to buy. The compensation which the public practice would otherwise have attracted is forfeited to the Treasury. The Minister's solution is ingenious. To the extent to which the practitioner not in the Service but called upon to buy a public practice is entitled of money which to him is a complete loss, to that extent there is money left in the compensation "left" to pay compensation which is not authorized by the Act. The Minister converts the proceeds of expropriation to relieve him of the necessity for amending the Act so as to pay compensation not provided for by the Act in its present form.

The Doctor's House

The Minister asserts the profession that a doctor's widow who puts up her home for auction, whoever may buy it, is not committing an offence.

His statement needs to be compared with the words of the Act, which defines an offence, without excluding the procedure of the auction sale, the selling of a house to an incoming practitioner at a price "substantially in excess of the consideration which might reasonably have been expected if the premises had not been used for the purposes of a medical practice" (Section 35 (3)).

When it suits him the Minister argues that the Act is for the Courts and not for him to interpret. But when he is seeking to apply professional fears he does not hesitate to produce an excellent interpretation of the Act even if a simple straightforward reading of the Act proves him to be wrong!

Remuneration

Whatever the form of Service, the range of remuneration of general practitioners is governed by the report of the Spens Committee, which the Minister has accepted in principle. For the profession to stand out for amendment of the Act will not affect the range of general practitioner remuneration.

An examination of the Minister's proposals reveals some interesting features:

The central pool will receive 18s. in respect of 95% of the population for two years only. Therefore, remuneration should be examined on the 95% assumption.

The more general practitioners who enter the Service as principals the greater the number of basic salaries to be paid and the less the capitation fee.

Conversely, the smaller the number of general practitioners who join the Service, the larger the capitation fee.

Nothing has been heard of the tapering capitation fee since the publication of the White Paper. It now returns in a new form. The remuneration for the first 1,000 patients works out at a capitation fee of 21s. 2d., the remuneration for every additional person on the list being 15s. 2d. if 17,900 principals join the Service, 17s. 3d. if 17,300 join, 15s. 4d. if 17,000 join, and so on. It will be seen from the figures given in para. 27 of the Minister's reply that the effect of the basic salary is to reduce the average payment per patient from 21s. 2d. for 1,000 patients to 16s. 8d. for a list of 4,000 patients. The basic salary of £300 a year will be paid to every general practitioner entering the Service, "subject to conditions to ensure that some reasonable minimum number of patients is accepted by such doctors within a reasonable period." The basic salary, it seems, is to be paid on the assumption that those who need it should not need it for long. The great majority of practitioners do not need it at all. The only argument ever used by a member of the Government in support of a universal basic salary is the one used by the Lord Chancellor in the House of Lords when he argued that the salary method was needed for the control of certification.

Comparison with Spens

Does the proposed remuneration square with the recommendations of the Spens Committee? That Committee

recommended in net figures and in terms of 1939 money values the following spread of professional remuneration:

75% of general practitioners should obtain over £1,000 per annum.
50% of general practitioners should obtain £1,300 per annum or over.
25% of general practitioners should obtain over £1,600 per annum.
Slightly less than 10% of general practitioners should obtain over £2,000 per annum.
A few general practitioners should obtain at least £2,500 per annum.

The betterment factor used by the Minister in the recent increase of the current insurance capitation fee to bring 1939 values up to current values was 30%. If this low figure is applied to the Spens recommendations we get:

75% of general practitioners should obtain over £1,300 per annum.
50% of general practitioners should obtain £1,690 per annum or over.
25% of general practitioners should obtain over £2,080 per annum.
Slightly less than 10% of general practitioners should obtain over £2,600 per annum.
A few general practitioners should obtain at least £3,250 per annum.

(These are net figures.)

In order to make these figures comparable with the Minister's present proposals, it is necessary to convert them into figures of gross income. If this is done, on the assumption that expenses amount to one-third of gross practice receipts, the Spens recommendations take the following form:

75% of general practitioners should obtain over £1,950 per annum.
50% of general practitioners should obtain £2,535 per annum or over.
25% of general practitioners should obtain over £3,120 per annum.
Slightly less than 10% of general practitioners should obtain over £3,900 per annum.
A few general practitioners should obtain at least £4,875 per annum.

(These are gross figures.)

How do the Minister's proposals compare with the Spens recommendations? The comparison is exceedingly difficult to make, though one or two calculations are suggestive:

According to Spens, 50% of the profession should receive a gross income of £2,535 or more a year.

The average number of insured persons on a doctor's list is at present approximately 1,000.

If 95% of the community use the new Service the average number is likely to be rather more than 2,000.

Thus the average income of insurance practitioners, taking the Minister's figure for a list of 2,000 patients, will be £1,816 gross (or approximately £1,200 net).

The average income for the "middle group," according to Spens, should be £2,535 gross. Although the average income is not necessarily equal to the middle income, the size of the margin between £2,535 and £1,816—£719—suggests that, even allowing for the Government contribution to superannuation, the Minister's proposals do not wholly fulfil the Spens Committee's recommendations in the middle ranges.

Again, slightly less than 10% of the profession should, according to Spens, receive over £3,900; yet the practitioner with the maximum on his list will receive only £3,332. This means that no practitioner in the public service devoting the whole of his time to that Service can possibly achieve the level of remuneration recommended for 10% of the profession. To reach the level of £4,875 recommended for the few is out of the question.

It cannot be pretended that an exact comparison between the Spens recommendations and the Minister's scale is possible at this stage, but it seems possible that the middle and certain that the higher ranges of remuneration recommended by the Spens Committee will not be achieved by the Minister's proposals.

Right of Appeal to the Courts

The Minister rejects the request of the profession.

This is the one point upon which the Minister was defeated in the Committee stage. He states that any other situation would be impossible. So the position remains that medical practice can be made virtually impossible for a medical practitioner whose name appears on the Medical Register, without his having the elementary right of appeal to the Courts. In the Northern Ireland Health Service Bill a practitioner aggrieved by any decision of the tribunal is given the right of appeal to the Courts.

Hospital and Specialist Services

The Minister is empowered to do this. He states that he would not be subject to hearing any views from the "Hospital Board"—a qualified body which might be hindered by his successors. "Where circumstances make it impossible to use the available private beds for the prescribed maximum charge." He also mentions a number of other points of view from the Nettlestone Committee. But the Minister's assurances are not binding. The Minister does not intend to take over the management of private hospitals, why does he propose to do so in the Act? Section 4 accommodation is developed, but the Minister or his successors to make any such arrangements can be reversed at any time. The Act is a State monopoly of hospitals.

LOCAL HEALTH AUTHORITY SERVICES**Health Committees**

The Minister has no powers of compulsion—to seek such powers—to ensure that local health committees members of the profession. The Minister refuses to ensure that local health authorities to appoint statutory committees and to refer to them all matters relating to their functions under the Act. The new committees, which are required to co-opt persons in addition. But the Minister refuses to ensure that the committees shall co-opt persons experienced in

Decentralization of Local Health Authority Services

The Minister is asked to provide compensation for county medical officers of health who lose a major part of their status as a result of schemes for the decentralization of local health services. This is a matter for the medical officers of those areas which are to be transferred to the medical officers of those areas. The Minister, however, has not considered the effects of the Act on the position

GENERAL

The Minister in his closing paragraphs that the Act is intended in the ultimate resort solely to the welfare of the men, women, and children of the country. Part of this programme is to ensure that the medical profession, for it knows that its work to the public if its members, become salaried officers of the State. The general practitioners shall no longer be paid by the State; that they shall set up an area only with the permission of a hospital monopoly and to render the medical profession these developments are towards the goal which the Minister has in mind. To use his own words, "We owe it to the public and to the medicine of the country to ensure that the medical profession of the country will co-operate with the State in the main objective, would be to ensure that the medical profession which is the public health."

In the long run the independence of medicine is no less important to the country than the independence of the judiciary. What the Act of Settlement secured for the judges is being swept away two centuries later for medicine, under the influence of a contemporary political fashion.

THE PLEBISCITE

There will be issued to every member of the profession Jan. 31, 1948, a plebiscite form. If a sufficient majority of the profession confirms the view which is here expressed and vote accordingly, the medical profession will be advised not to accept service under the Act in its present form. The profession will be asked to accept the verdict of the majority that majority is of sufficient size. Whatever the result, a doctor will be advised not to render service to his patients or not to continue with his professional work. The position is well summed up in the statement which the Council of the Association has already issued:

"If the profession decides against service consultants and specialists will be advised to continue with their hospital work, meanwhile refraining from entering into contract with regional hospital boards; general practitioners will be advised to continue with their practices but without entering into contract with local executive councils; public health officers will be advised to continue with their work under local authorities. Parliament has given to every doctor the right freely to enter or not to enter the Service. Indeed the Minister, in his reply, draws attention to this right. The medical profession, while never willing to withdraw its services from the public, is fully entitled to say that the State Service offered is, in its considered view, opposed to the best interests of the public and the profession."

"The task now before the profession is to strip the non-essentials from the essentials, to distinguish between the shadow and the substance. Despite the Minister's promise that if convinced he would seek amendment of the Act, he has remained unconvinced and impervious to argument, and thus for nearly a year we have worked at the conference table to no purpose."

"There remains one final question and one central issue. Does the Service as described by the Minister conflict with the traditions and standards of a great profession? The answer is only one the Council of the Association can give to this question. It does so conflict."

Conclusion

Parliament has given every doctor the right to decide whether to enter the Service or not to enter it. The Minister of Health has agreed that the profession is entitled to decide the question collectively as well as individually. Indeed, it is obvious that in such a matter, which is of the highest professional and national concern, doctors, like other workers, are entitled to look to their leaders for guidance.

The British Medical Association now offers such guidance. It does so neither lightly nor recklessly but after prolonged study of all the issues.

Firmly believing that the National Health Service as at present constituted will undermine the independence which in all ages medicine has needed for its work, and that it is therefore contrary to the interests of both patients and doctors alike, the British Medical Association recommends the medical profession to give expression to this view in its votes in the forthcoming plebiscite.

RESOLUTION BY REPRESENTATIVE MEETING

The following resolution was carried by the Special Representative Meeting on Jan. 8:

The elected Representatives of the medical profession in Great Britain and Northern Ireland, meeting in London this 8th day of January, 1948, solemnly declare that in their considered opinion the National Health Service Act, 1946, in its present form is so grossly at variance with the essential principles of our profession that it should be rejected absolutely by all practitioners.

PHYSICAL EDUCATION IN THE NATIONAL HEALTH SCHEME

A five-day conference on remedial gymnastics was held under the auspices of the Fine Physical Education Association in London in the first week of the New Year. An intensive programme of lectures, demonstrations, and visits was carried through. The opening address was given by Dr. Harold Balme, medical officer in charge of rehabilitation, Ministry of Health, whose subject was the place of remedial gymnastics in the National Health Service scheme.

Remedial gymnastics, said Dr. Balme, started in this country as a means of dealing with congenital deformities and postural defects. Its emergence into a wider field was due largely to the report of the B.M.A. Committee on Fractures, which recommended the development of fracture clinics and the use of rehabilitation methods, particularly remedial gymnastics, in dealing with industrial injuries. Similar recommendations were made in 1916 by the departmental committee of inquiry into arrangements for the restoration of the working capacity of persons injured by accidents. During the recent war remedial gymnastics extended into a still wider field, including the treatment not only of orthopaedic disabilities but of any disorder, whether medical or surgical, which might lead to permanent disability.

In the proposed National Health Service remedial gymnastics had a vital part to play. Any child born with a deformity should receive continuous gymnastic guidance during school life and later. There were now some 500 hospitals in which the general idea of rehabilitation had been accepted to the extent of allocating separate departments for this work and appointing rehabilitation officers, remedial gymnasts, and occupational therapists. In the future the remedial gymnast must work in children's clinics, where he or more often she—would be able to deal with deformities and postural defects. No remedial gymnast, said Dr. Balme, need fear that under the new scheme she or he would not find an important place.

Postural Defects

The programme of lectures and demonstrations at the conference included a lecture by Prof. A. B. Appleton on feet and posture and several demonstrations on the remedial treatment of postural foot defects in school-children. Dr. F. S. Cooley, director of the physical treatment department at King's College Hospital, spoke on postural defects of the spine. Severe structural scoliosis was a problem ten years ago, but comparatively few cases were seen to-day. There were, however, a large group of cases of round back or kyphosis. This condition started early in childhood, and if it was to be remedied physical education must begin in the nursery. In modern orthopaedic books there were many pages on scoliosis, but the antero-posterior curvature of the spine was largely disregarded. The condition often arose in debilitated children, and in adolescence was often associated with impaired respiratory function. He thought that this condition of lordosis had frequently been missed in school medical examinations because while the front and back of the child were inspected no regard was paid to the sideways position, in which the abnormal curvature became apparent.

The disorder was a progressive one. He thought that many such cases might be explained by the frequency of cold and feverish conditions in young children. They were kept in bed for a day or two, but as soon as the temperature subsided they were allowed to get up; and then, owing to weak muscles, they tended to adopt the "slump posture," which became habitual. The child with adenoids and persistent toxic absorption from the nose and throat quickly became fatigued. The spine came out still more with the wedging of the vertebrae, and the round shoulders, "slump posture," flat pectorals, and long dorsal kyphosis became permanent. The problem was one of physical education in the widest sense. Any eye trouble should be corrected, for some of the slumping might be attributed to visual difficulty at the desk. Faulty breathing should be corrected. The child's environment should be studied, and he should be examined at work and play, and particularly when he was tired. Adequate rest, not on an arbitrary basis but according to the needs of the individual child, should be

enjoined. If a child got to secondary school age with a round back nothing could correct the real evil, namely, the bony change, though it was true that the appearance could be improved by exercises which encouraged proper muscular tone and carriage.

THE CHILD IN INDUSTRY

The Conference of Educational Associations which was held in London at the beginning of January included a discussion arranged by the Medical Officers of Schools Association, when the subject of the transition from school to industry was introduced by Dr. T. Lloyd Davies, an industrial medical officer of Nottingham. Dr. R. E. Smith (Rugby) presided.

Dr. Lloyd Davies said that 280,000 boys and 270,000 girls entered industry (using the word to include all profitable employment) between the ages of 14 and 17 in 1946. In industry, as compared with school life, the young person found the hours longer, with fewer breaks, the work more monotonous, and the supervision less close. The nutrition of the child was apt to suffer with the end of school meals and milk, and there was likely to be an excess of carbohydrates in the diet. By the time the child entered industry he had come to the end of his second big spurt in the rate of growth. At about the age of 14 boys began to be taller and heavier than girls, who up to that age had had the advantage in these respects. The raising of the school age would make a considerable difference to the stage of maturity in which the majority of young people entered industry.

Speaking from his own experience as an industrial medical officer, Dr. Lloyd Davies described "the pathetic scraps of humanity" who sometimes presented themselves for employment—undeveloped physically and in every respect. For some rather obscure reason children who applied for work in offices were on the whole graded higher on intelligence tests than those who applied for work in factories. These children were much more sophisticated than the public-school group; they came from a less well protected environment, and sometimes they had questionable values and standards. They were often difficult, being shy and suspicious, but if handled properly their response was whole-hearted. When there were defects in the home it was not uncommon to find these children on the verge of social delinquency. Their reading matter often consisted of journals devoted to love or crime or both, sometimes with advertisements having an unpleasant sex appeal.

If these children were to be asked what they sought in employment it would be found that most of them were out for a safe job. This was a repercussion of parental unemployment in the 'thirties. It created a deep impression in the family when the father was out of work, for if ineffective from the economic point of view he was likely also to be ineffective from the social and disciplinary point of view, and the psychological balance of the family was upset. Some of the children were more concerned about those with whom they would have to work than about the nature of the job itself; with others it was the reverse, and doubtless there were intermediate grades. In repetitive jobs girls were more at home than boys, being more skilful in escapism, usually an escape to love fantasies and the making of a home of their own. Many boys could not stand repetitive jobs, and this dislike might be reflected in high accident rates or in strikes. Dr. Lloyd Davies reminded the meeting that in one year 32 boys and 4 girls under 18 were killed in factories and mills, and 21,000 boys and 7,000 girls injured to such an extent as to necessitate absence from work for more than three days. Of machine accidents, 16% involved the injury of persons under 18.

The fact remained that the vast majority of children in this country must make the transition from school to industry, the period of growth from childhood to adult life being passed partly at school and partly in industry. Educationists began the job of training them for citizenship, and industry had the responsibility of creating the conditions under which development in that direction was completed. He welcomed the Education Act, 1944, in that it made possible a prolongation of school discipline and oversight into a later period, so that the transition at a critical time in the life of the growing child was made less abrupt and involved less peril for the future.

MEDICAL PRACTITIONERS AND PHARMACISTS ACT

REGISTRATION PROCEDURE

It is noted the following statement on

... country possessing only foreign ... temporarily admitted to the British ... arrangements have for some ... to their future after the termina- ... Dec. 31, 1947. The Medical ... Pharmacists with Foreign Qualifications

Another permanent change in the law effected by the Act enables the Pharmaceutical Society to register pharmacists qualified abroad either without examination and compliance with normal requirements as to training and study, or subject to such modified examination and other conditions as they think proper. This replaces an existing provision limited to holders of "Colonial" Diplomas whom the Society were empowered to register without examination. Pharmacists qualified abroad who are temporarily registered under the Defence Regulations are eligible for consideration. In the meantime, their temporary registration continues for six months from the passing of the Act.

Preparations and Appliances

A SPRAY DEVICE FOR SURFACE ANALGESIA

Dr. A. OWEN-FLOOD, Hornsey, writes: The attainment of effective analgesia of the pharynx and larynx, and especially in the more extensive preparation for bronchoscopy, is seldom easy and, as evidenced by the obvious distress of many patients undergoing the ordeal of this trying examination, not always successful.

Adequate analgesia of the more accessible structures like the mouth, pharynx, and fauces requires no great effort or skill, but the larynx, epiglottis, vocal cords, and trachea, protected as they are by the shelving parts of the tongue base and the powerful reflexes guarding these vital channels, call for a more expert technique.

Two main difficulties are here encountered: The patient, making every effort to resist invasion of the foreign bodies—

the spatula (which is invariably too short) on his tongue and the liquid spray down his throat—renders the view of the larynx imperfect and the saturation of the whole area with the analgesic solution a hit-or-miss affair. The "saying 'Ah!'" technique, by which prolonged exclamation the patient exposes deep structures, is well enough in itself if there is uniformity in its performance by all patients, but experience shows that it can vary from a faint mouse-like squeak to a bull bellow.

I have chosen Macintosh's laryngoscope for the spray attachment illustrated, because it lends itself more readily to this adaptation than the other makes, allowing a ... nated

view of the epiglottis and vocal cords, at the same time exerting an even pressure on the whole surface of the tongue. It also steadies the organ and holds it firmly out of the line of vision.

The tongue-piece is composed of two thin plates through which is inserted a fine-spray nozzle which emerges about an inch (2.5 cm.) from the end of the spatula, at a point where it curves slightly downwards. This position gives a maximum spread to the spray, allowing also a quantity to dribble and desiccate the inner surface of the epiglottis and the vallecula. At the rear end of the tongue-piece the spray tube joins a small metal cylinder in a gentle curve, to avoid coming into the line of vision, and to render clearing its stuffed lumen by suction thread a simple operation should it be necessary.

The cylinder is composed of three parts: a lid containing the spray mechanism and inflator apparatus, the body to which it is screwed in an airtight joint, and its glass-lined container charged with the anaesthetic solution. Cleansing is facilitated and corrosive action by this agent is thus prevented.

The surface anaesthesia, thanks to the excellent properties of the Laryner-spr, becomes smooth and comfortable for the patient. With a few squirts into the mouth the tongue-piece can be passed without gagging, and an adequate analgesia is obtained of all structures in view. With fair relaxation of the vocal cords some of the agent can be sprayed directly down the trachea, thus avoiding the necessity for the injection of the fluid. Agent directed into the larynx by piercing the crico-thyroid membrane is an operation distressing to the patient as well as hazardous.

Reports of Societies

MENSTRUAL DISORDERS IN RELATION TO GENERAL MEDICINE

The last Hysterian Society meeting of 1947 was devoted to a discussion of menstrual disorders in relation to general medicine. Mr. ARTHUR L. ROCHF. presided.

Mr. ALFRED W. BOURNE, in opening, excluded from the discussion disorders due to general pelvic conditions. Where there was no local disease he believed that the majority of manifestations of menstrual disorder, whether amenorrhoea or excessive loss or pain, were due to disturbances of function of the anterior pituitary. How the anterior pituitary exercised such a varied function was one of the biggest problems in medicine. In conditions of anxiety, grief, and fear the gland seemed to go wrong, as was shown by its gonadotrophic action on the ovary. Certain cases of amenorrhoea were clearly associated with emotional disturbance. How was it that the anterior lobe could be disturbed in the absence of any ascertainable hormonal influence? He supposed that the effect of emotional distress on the function of the gland must be explained by the influence of nerve fibres coming down the pedicle from the thalamus, but that only put the problem one stage further back. He believed that the function of the lobe was so strongly under the influence of mental and emotional conditions that it was sensitive to all that a woman feared and equally to all that excited her. He understood, too, that at least fourteen hormones had been found to be derived from the cells in this tiny lobe of the sella turcica.

Dr. EDWARD SJARRP described a small series of cases seen in general practice. Eight cases of spasmodic or intrinsic dysmenorrhoea had not responded to hormone treatment, a general tonic, and advice about fresh air and exercise. Then he had a talk with each patient, trying to persuade her that her dysmenorrhoea did not mean that she was abnormal, and that she must not allow it to "get her down." This was more effective: one patient was much improved and apparently cured, and three others were improved to the extent that it was no longer necessary for them to stay away from work at the monthly period; the remainder were no better. His second group consisted of eight cases of amenorrhoea and oligomenorrhoea; some of them improved after treatment with stilboestrol. His third group consisted of eight cases of metrorrhagia and menorrhagia, and in seven, the condition occurred towards the

end of reproductive life. Four had volunteered the information that their loss was always very much heavier when they were emotionally upset, and five of them had a very unsatisfactory emotional background.

One of these women had been saddled with an ungrateful and unsatisfactory father-in-law, entailing a great increase in her work and threatening to come between her and her husband. He was eventually disposed of, and her periods returned to normal. Another was a woman who was in continual anxiety, separated from her husband, and engaged in work which she thought beneath her but which was necessary for the support of her family. So far her periods had been unaffected by any sort of treatment. Another was a woman aged 42 whose husband developed tuberculosis of the spine and whose daughter made an unsatisfactory marriage. Her husband was now very much better and she was improving without treatment. Another woman, aged 32, was anxious about her husband, who was a civil air pilot and absent for long periods. She was sterile, and here again treatment had no effect. Another was a woman aged 44 who had been twice married. Her second husband became a chronic invalid almost immediately after marriage, and the wife devoted her life to nursing him. He died after twelve years. During the last five years there had been no sexual intercourse, but the husband's invalidism was not such as to prevent him from taking a mistress, unknown to her, during the last eight years, a fact which the wife did not discover until she was a widow. After she recovered from her distress and anger she herself took a lover, and her periods had been regular ever since.

These cases illustrated the futility of treating metrorrhagia and menorrhagia as anything more than symptoms. It was significant that in five of these eight cases the husband loomed large in the picture, either owing to his absence or his actions. Happiness in marriage was closely related to normal menstrual function.

Mr. JOHN HOWKINS spoke of girls in the Services during the war who came up for treatment owing to menstrual disorders. He believed that the mothers of these young women had a good deal to do with their condition. They were apt to relate with sadistic delight what had happened to them, and a number of the girls were "auto-suggested" into dysmenorrhoea. He expressed some scepticism about the claims made for drugs in the treatment of these conditions. One disease which was of some interest in this connexion was tuberculosis of the genital tract. Attention had been drawn to the number of cases of sterility in which on diagnostic endometrial biopsy giant cells had been discovered. This question of tuberculosis of the endometrium was a very important one. It used to be said that when a woman who had pulmonary tuberculosis developed amenorrhoea or menorrhagia it was a sign that she had genital tuberculosis. It was worth while to draw attention to the possibility of tuberculosis of the genital tract.

Mr. V. B. GREEN-ARMYtage quoted some Biblical and Shakespearean references to menstrual trouble, notably the case of the woman with the issue of blood as described in St. Mark's gospel and certain passages in *Romeo and Juliet* and *The Winter's Tale*.

After some further discussion Mr. ALECK BOURNE, in reply, suggested that the completely happy individual, perfectly adjusted to environment, and exalted, could never be ill. Their trouble as physicians was that they could not prescribe the initial therapy—happiness—for all functional diseases. With regard to tuberculous salpingitis, a recent writer on the subject, in examining the biopsies of women who suffered from sterility, found that 4% showed giant cell systems. It might not be the true deduction that a giant cell in the endometrium necessarily meant tubercle, but it was the fact that tuberculous endometritis was much commoner than many thought.

The first ordinary meeting of the newly formed Medical Subsection of the Library Association was held at the National Institute for Medical Research on Jan. 2. Welcoming the seventy or more members and guests, Dr. C. R. Harrington, the director of the Institute, spoke of the increasingly important part played by library services in the modern world and of the invaluable aid that specially trained librarians could give to those engaged in medical practice and research. Dr. G. Popjak gave an illuminating talk on recent developments in nuclear physics and their medical applications, and Miss Ethel Wigmore described the work of the library. A conducted tour followed, and the visitors displayed a special interest in the system of indexing current periodical literature and reprints.

Correspondence

National Health Service

At the meeting on 15p. 4 Dr. Guy Dun spoke of the importance of the plebiscite being legally binding. He proposed that the proposal that will achieve the purpose of the vote against the N.H.S., is of course, to avoid putting the fear of being in the

position of a Ministerial agreement we sign it but it is not binding. These papers are then collected by the Secretary (by personal application) and the papers are collected. The B.M.A. Council should be asked to collect, and if our majority were not in favour of them *not entering the scheme* and if Mr. Bevan. If our majority is not in favour of them to be returned to their owners.

The fear of revoking between our plebiscite and the Act, and if made known early enough the vote of "no" into the plebiscite figures, we hope to specialists and G.P.s alike.—I am, etc.,

R. MUTTON.

If the majority of us G.P.s are opposed to the National Health Service, surely if we refuse to join the Service, surely the Government will be forced to work and an amendment will be forced. We are not sure of the strength of will in other parts of the country. We fear that the Service may increase to a rapid flow, followed by a rapid decline.

As a part of the questionnaire the profession be asked to state if they are opposed to the Service as it stands, and if they are of the same opinion, will you bind yourself to the Service until acceptable terms are agreed by the Committee? If 60% bound themselves thus, the Government would be immensely strengthened.—I am, etc.,

G. H. GIBBINS.

As the last B.M.A. plebiscite made it clear that the profession held a majority opinion against this Act, the intervention of the three Presidents the Minister of Health to lay more of his cards on the table. After a year's delay there is still no amendment of the Act. Surely therefore, the plebiscite still holds? And if we must have a decision, why should it be decided into it within a month? As the Act is being delayed for a year why should we not wait for six months and hold our plebiscite

As a manifesto by the Minister himself to the individual doctor—suggesting an amendment between the general practitioner and the Minister of Health, a superficially alluring picture of the Service under the Act and thus the Minister of Health from which there is no doubt that he is left in the last resort to the Minister of Health. This would be impossible to compare with any form of ultimate jurisdiction. This would enable the Minister to amend any or all the terms of the Service, and we should have

As a manifesto that an appeal can be made to the Minister of Health any decision of the Minister of Health is surely not only a decision of the Minister of Health, etc.,

W. H. SPOON.

SIR.—The Minister of Health has now clearly revealed his intentions, and it is up to the profession to act decisively. Our only weapon is a majority decision to refuse to enter the new Service, but individual doctors cannot be expected to do this without complete confidence that the majority of their colleagues are doing likewise. In order to ensure this confidence I propose that the Secretary of the B.M.A. should send to every member of the profession the following two documents. The first should be addressed to the Minister of Health and should be signed by all doctors agreeing to the scheme and should be undated, and then returned to the Secretary of the B.M.A. Subject to revision by legal experts, it should read somewhat as follows:

"I (Dr. X), being in active practice as a general practitioner, or consultant, or employed by a hospital or local authority in a full-time capacity, or being retired, do hereby inform the Minister of Health that I refuse to accept service under the National Health Service Act, 1946.

"This document must be taken as cancelling any previous application to serve under the Act that I may have signed.

"Signed, Dr. X."

The second document should be addressed to the individual doctor concerned and should be signed by the Secretary of the B.M.A. and should give him a solemn promise that the preceding document, if signed by him and returned to the Secretary of the B.M.A., would not be used unless at least 50% of the entire profession were to sign and return similar forms before the closing date. It should also be required that at least 60% of the general practitioners should sign such forms, and that the forms signed by members of the special groups such as consultants (except those retired) should not be used unless at least 40% of the doctors in the same group had signed and returned similar forms. It should also be made clear that a doctor who had signed such a form would still be free in the meantime provisionally to accept service under the Act, but that such acceptance would automatically be cancelled if the above document were to be used, in the manner to be described, by the Secretary of the B.M.A.

Assuming that the above conditions were fulfilled, they should be retained by the Secretary of the B.M.A. until the closing date for applications, though the existence of the forms and their numbers could be made public. If the Minister remained impassive they would then be dated and delivered to the Minister on the closing date, and each doctor concerned would be individually informed of the fact by the next morning's post.—I am, etc.,

Newport, Mon.

G. W. HOARE.

SIR.—Many like myself must have a profound feeling of dissatisfaction at the results of the negotiations between the Minister of Health and the B.M.A.—dissatisfaction both with the results, which amount to *nil*, and with the fact that these negotiations were allowed to drag on for so many months while the profession was kept in complete ignorance of what was happening behind the "iron curtain." The impressions formed are that the Minister of Health was gaining time on his side and that the B.M.A. was at fault in submitting to such a prolonged period of negotiation when it was obvious, as the results prove, that no headway was being made. These results now circulated to the profession could surely have been arrived at in as many weeks as it has taken months. Can there be any reasonable explanation for this delay?

I am sure there is a growing feeling of dissatisfaction against the "kid-glove" methods of approach to the Minister of Health by the B.M.A.

Many of Mr. Bevan's statements are very misleading, especially to the general public. One such statement, that doctor are entirely free to join the Service or remain out of it, is very misleading. The "pistol" is at our heads and we are asked to "sign on the dotted line" and give up our freedom or not to sign and give up our possibilities of making a living.

If we are compelled to accept service under the Act as it now stands in order to make a living, probably the greater percentage of doctors will enter the Service under protest and with a disgruntled feeling. It seems a pity that Mr. Bevan has shown so little consideration for the principles which the profession has aimed at maintaining, not with any ulterior motive

and that he would have the opportunity of appealing our modest desires, which he could very easily have done and so ensured a Service which would be contented and contented profession. My only conclusion is that the membership and understanding have been overruled by party political considerations by which we will be for ever controlled if we accept service under the Act.

One would think that resignations from our present N.H.I. contract would influence Mr. Bevan to change his mind as to the effect of such resignations did on a previous occasion. There is little time left for such action, and it would be a pity to let it pass without delay. —I am, etc.,

Stapleford

A. B. TAYLOR.

Sir,—The only reason for a plebiscite now is to confirm the previous decision. This can be done emphatically if:

(a) New members of the B.M.A. and members who do not read the *Times* are reached by clear brief leaflets stating our objections to the Act, as it exists; publishing the proposed Government policy, i.e., a full-time salaried Service, which obviously is not the Minister's intimate aim; and pointing out that it is in the power to attain this with his dictatorial powers under the Act and that there is no appeal against his decision.

(b) Doctors are told it difficult to decide, owing to financial reasons, the given costs of the Lighting Fund, its source, and whether or how it will be used.

(c) An answer is given to the many who say, "I would vote against it if I knew what my neighbours are doing."

(d) There is a guarantee that no agency or group will be allowed to pull another red-herring after the plebiscite, no matter how good their intentions.

(e) It is pointed out how a handsome capitation was offered to get doctors into N.H.I. in 1912 and how it was "adjusted" to less than 50% of that sum in due course. This bait is offered again with the significant sentence, "But in two years' time that position will be reviewed."

(f) It is pointed out that the silky "General comments of the Minister addressed to the individual doctor" were obviously not written by Mr. Bevan's pen. They remind one of Hitler's propaganda facts before invading a small neighbour. Neither was para. 71 of the Minister's report, which might have been written by a Florence Nightingale. It even promises amending Acts!

(g) Finally, the actual plebiscite paper is made simple and clear. (It is generally agreed the last one was misleading to many.) —I am, etc.,

Merton

THOMAS J. CRONIN.

Sir, Dr. E. Billing (Jan. 3, p. 25) writes, "The decision should be taken on the vote of private practitioners only (consultant and general, whose future is at stake," and gives a list of various publicly paid doctors whose "votes should not influence the issue." May I, a retired G.P., go further and say that the votes of retired men should for obvious reasons (political or family) be entirely left out of the count, as our future is not at stake and we can, so far as is possible, leave the future and the reputation of the profession in the hands of its acting members.—I am, etc.,

Credon, Devon

E. PROTHIERO SMITH.

Sir,—The preamble to the circulated pamphlets of the Negotiating Committee's case and the Minister's reply asks the profession to study these preparatory to a plebiscite being taken. For this purpose preliminary and divisional meetings are being held for exposition and discussion. I think a serious error is being committed in not also circulating to the profession the exact terms on which a plebiscite will be taken.

The terms for the plebiscite are *all-important*; they should be the subject of careful discussion by the profession and should be agreed by the profession before being sent out for voting. For instance, it may be impossible for a man to give an honest "yes" or "no" vote on whether he will serve under the Act as it now is. He could only do so if assured that action will only follow a unanimous decision. It is quite clear that there will not be a unanimous decision, and in this case a man standing to his vote of refusal to serve might well find himself

faced with economic ruin. Such a strain on him would be intolerable and should not be required. It would be better for the plebiscite terms to be much weaker but capable of being carried out, otherwise an honourable man must abstain from voting. I would suggest that the plebiscite should include a vote that he would serve, but with disapproval of the offending clauses and intent to work for their amendment. The exact wording should be the subject of careful discussion. Such voting would have great weight because of its obvious integrity and as indicating that service would be given under duress.—I am, etc.,

Worthing

W. O. PITT.

Sir,—The Minister's reply may be summarized as soft soap and personal promises. I do not believe he personally wrote the former; the phrasology simply is not his; and the promises are useless, for apart from any question of good faith he may be dead or dismissed to-morrow. The only thing that counts is the Act. The Act in its present form is anathema to us. The trap is wide open. Once we are in we are finished; this is our last chance. Sell your practice (note the blackmail: no compensation if not in by July 5) and accept a basic salary (stated categorically by the Lord Chancellor as designed to control our certification), and you are a slave.

Certification? What a thought! What a weapon! If we stop issuing certificates the whole machinery of the top-heavy bureaucratic mass stops dead as completely as the kingdom in the fairy story. "No amending Act: no certificates." Not a bad slogan, my brothers and sisters.—I am, etc.,

Devon

W. F. BENSTED-SMITH.

Sir,—Time is getting short. Overmuch has been said about some aspects of the National Health Service and insufficient about others. We still have no idea of what our income will be for the following reasons: (1) The rate of remuneration depends upon the percentage of population insured; (2) the greater the percentage insured the less will be the number of private patients who can afford to pay us.

We still know nothing definite about compensation. Is it to be twice average gross of the last three years? If it is for any earlier period then it amounts to capital appropriation, because no allowance is made for practice growth in recently acquired practices. For example, a panel practice is bought in 1945 and a private practice is built up in addition subsequently. Is the compensation only to be for the panel value in 1939 with no allowance for existing private income?

The majority of practitioners in N.H.I. work must feel how much more satisfactory it is to treat private patients, because private practice is recompensed in proportion to output whereas N.H.I. work, hedged about as it is with irksome restrictions, leaves one with the feeling that one is constantly being imposed upon by the irresponsibles and neurotics.

I see that the Minister intends to arbitrarily decide what certificates must be issued free. I should hate to be dependent on his decision when I think of the numerous reasons for certificates arising out of rationing and control.

The present N.H. system, in which the doctor is under contract with the societies instead of dealing direct with the public as regards payment, is unsatisfactory enough. Why not seize the present opportunity to start afresh? Follow the example of the medical profession in the Department of War, S. France, where the doctor is paid direct by the patient, who is thus made to realize that service costs money and is not to be dissipated on aspirins and bromide. The patient then collects what he can from his society, which in turn learns to recognize the bad sheep in its fold and deals with them accordingly.

Substitute the Government for the society in this proposal and let matters take their course. The net effect of the compulsory levy of 6s. 2d. weekly, which all self-employed men, including myself, will have to pay, and the resulting experience of the scheme by the public will no doubt cause many second thoughts and result in an electoral kick in the pants for this or any Government which persists in it.

Are we going to be such fools as to voluntarily relinquish our present degree of freedom, and income of known dimensions, for more restrictions and absolute doubt about our future?—I am, etc.,

Bournemouth

A. R. THATCHER.

...the new National Health Service "is of force" and suggests that the points in the dispute are determined by the Government. Having carefully read Mr. Bevan's reply, your leading article of Dec. 26, 1947, and the letters in your issue of January with *The Times*. For what reason do you find fault with Mr. Bevan and his Government's financial future and the future of the National Health Service? We, in your issue are asked to "compromise" but say that our freedom is in jeopardy. It faces squarely the fact that we cannot only take place at the expense of the State but what he likes. Surely the whole of the country is in the direction of increasing organization to recognize this because we dislike the present process entails? Would it not be a part in the very difficult problem of destroying individual liberty and

...to refuse co-operation on the basis of playing a confidence trick on us. We shall be forced to accept a full-time service. Surely if any Minister were to attempt this we should then have a major part of the stake in our hands. Should we have the public behind us that they have received a satisfactory result?

...to have gone out of his way to put our views on the B.M.A. platform have taken no part in it. We have heard appeals for democracy. This emotional conflict of the movement and commands little support in the public mind. The Government have disposed of any illusion by rousing against the present Government "freedom versus bureaucracy." The average citizen must somehow be combined. Let us contribute to the solution of this problem.

...in the policy advocated by the Government I foresee an ignominious repetition of the past.

F. E. S. HATFIELD.

...agreement with Dr. L. P. Gray (p. 107) that direction of any labour is wrong. The industrial action to further political and sectional interests as he appears to intend to do. Then I submit, we should not be setting a very dangerous

...there should be no politics, and work let us be as forceful as we can. As doctors we have every right to sabotage the Government, actual or alleged, when as compared with those wishes bad for the profession, both of which we have the right to do. Outside our special province we are the weapon of the sabot.—I am, etc.,

T. J. TAUNTON.

Dr. F. W. Vincent (*Supplement*, Dec. 27, 1947) says that the Government's estimate of the cost of the new service is £66,000,000. Even if the £66,000,000 was the actual cost, it can hardly be taken in value since then and it is worth the cost when compensation is paid.

...a practice would normally be expected to be a full-time service, whereas compensation is fixed. This is a very serious matter for the G.P.s, who must be paid for their services. We should not let the Government have the last word. It is contended that

the country cannot afford to spend so much money at this time. It is further proof that this is not the moment to introduce such a costly service, the success of which is by no means certain.—I am, etc.,

Musselburgh, Midlothian.

JAMES SHARP.

SIR.—In the *Supplement* of Nov. 1, 1947 (p. 100), a report of the Ophthalmic Group Committee appears in which it is stated that in the view of the Ministry of Health there was no case for the compensation of specialists for their practices for the reason that, "in so far as consultant and specialist practices might continue to be bought and sold, the National Health Service Act would not prevent the continuance of this custom." If this refers to "State" practices, it is, to say the least, a very curious anomaly. If on the other hand it refers only to private practices, the fallacy in the argument is obvious.

On receiving the report of the Negotiating Committee I naturally expected to find some clarification of this position. It appears, however, that this cynical disregard of the elementary principles of equity is not considered of sufficient importance to be worth a mention. Nor is the matter mentioned in the Minister's statement, from which one would gather that all doctors who elect to join the Service on the appointed day will receive compensation.

The report of the Negotiating Committee is stated to give all the information at present available. It is only to be assumed, therefore, that this matter, in common with most of the regulations, etc., concerned with the specialist services under the Act, is still under discussion. If this be the case, it is surely premature to hold a plebiscite before every member of the profession has had an opportunity of studying the complete regulations of the Act in their final form.—I am, etc.,

Plymouth.

P. R. GREEVES.

SIR.—In the *Journal* of Sept. 7, 1946 (p. 342), you were good enough to publish a letter in which I tried to show that the essential difference between the Minister of Health and ourselves was one of policy rather than of principle. No one attempted to refute my argument at the time, and I refer to it because your able leader (Dec. 27, 1947, p. 1037), together with the Council's statement (p. 1046), appear to confirm my contention, for it is because the National Health Service Act is regarded as "the first and irrevocable step towards a whole-time State service" that we are invited to refuse service under the Act.

Socialist policy has always included a whole-time State service, and in 1945, when the present Government was elected on a clearly defined Socialist programme, many of us expected, and feared, that the new National Health Service would be according to plan and were astonished and relieved when Mr. Bevan's Bill proved to be merely a pale pink edition of the measures introduced by his predecessor, which, be it remembered, was an essential part of the Beveridge Plan accepted by all parties.

I am not a Socialist, and I loathe the idea of a whole-time State service, but it is advisable not to allow the violence of our emotions to interfere with the clarity of our thought. It is unfortunate that so few people recognize the fact that we are living in a period of revolution, as real as those of France or Russia, happily unaccompanied by the bloodshed and expropriation which disgraced them, but every whit as real. The party which now rules us has not lost a by-election, has nationalized the banks, the mines, and the railways in spite of all opposition, yet we are invited by our leaders to oppose a Government which has triumphed thus far because it has taken "the first step" towards nationalizing our profession. Has the B.M.A. Council forgotten King Canute and Mrs. Partington?

The Minister has promised that he will amend such portions of the Act as are found to be unworkable and asks us to co-operate with him in working it on those terms. As an alternative to the recommendations of the Council, with all respect, I venture to suggest that we take him at his word. The Defence Fund has ample funds to pay the expense of taking a test case to the House of Lords, and if one may judge from letters in the *B.M.J.* there should be fierce competition among the fire-eaters for the honour of being the principal figure in the case.

Section 36 (2) suggests that the Minister estimates that about 19,000 practitioners will be necessary to work the Act. Assuming that he has obtained that number of signatures on the appointed day, he will find himself in the position of being legally liable to

provide free medical attendance on about 45 million people and dependent on those amenities to enable him to fulfil his contract. If we co-operate with him, within a year or two we shall be in a very powerful position, for even a Socialist Minister of Health cannot afford to exclude several thousand medical practitioners to enable him to meet his obligations. Panel practitioners have proved at least once that it is possible to combine and force a Minister to listen to reason, and the power of the profession in the N.H.S. will be far greater than in National Health Insurance.

I now appeal to remember 1911 and 1912. Everything that has been said against the N.H.I. Act was said then against the N.H.I. Act—except that. And in those far-off days of freedom Lloyd George's Act was not even more revolutionary than Bevan's does to-day. The B.M.A. put up a stout fight and won five rounds out of six, and Bevan's side pleaded a not to take service "except on terms in accordance with the Association's policy." The Council then, as now, thought that the profession could successfully oppose an Act of Parliament, and laid out hopes to win the sixth round—and there was a knock-out blow. Then we had a powerful Press and a large number of public bodies, and to-day we have neither.

It is shown by the fact that the profession is as united now as it was in 1912, that evidence is evidence of that. In the questionnaire of 1947, 2,500 men and women took the trouble to answer forty-one questions, of which are the crucial points to-day. More than one-third are in favour of payment by basic salary plus expiation fee. More than one-half expressed their opinion that the Minister's "idea" proposed was reasonable and that the sale and purchase of practices should be abandoned. Is it likely that all these people have changed their minds? Nothing new has been said by anybody to induce them to do so.

Let us face facts. The Minister has at his disposal the sum of £20,000,000 with which to compensate for the loss of the sale of the goodwill of their practices those men and women whose names are on the lists of Executive Councils on the appointed day, and those only. How many of us can afford to take the risk of losing his or her share of this? We know that few of us can do so, and, however fine it may be to reflect on and talk about the "traditions and standards of our great profession," most of us have to earn our living in order to practise it, and that stark fact is the basic reason why we cannot refuse to serve.

None of the disasters predicted in 1912 materialized and we made the National Health Insurance Act a success, a benefit to the public and to the profession, and it is because of my long experience in that service that I am convinced that we shall be able to serve in the National Health Service without sacrificing any of our standards or being false to our traditions.—I am, etc.,

SYDNEY R. WILLIAMS.

Redditch, S. Dorch.

Sir,—The most obvious way to defeat the machinations of the Minister of Health is to reduce as soon as possible the number of practitioners who have no vested interests. I would suggest that all present practitioners and firms in partnership who are anxious to maintain the status quo ante do their utmost to take a partner and make him or her a "Have" instead of a "Have-not." Mr. Bevan is relying on the latter in the main to implement the Act. It is worth while making some pecuniary sacrifice to deprive him of his recruits and safeguard the future of the general practitioner and the public.—I am, etc.,

LEONARD LEY.

Great Yarmouth

Sir,—After a careful study of the Negotiating Committee's statement and the Minister of Health's reply, together with the Press (medical and lay) reactions over the week-end, one is still left in a somewhat perplexed state of mind. The *Lancet* comes out with the advice, "Trust the Minister," and makes the plain statement that because in the past we have sponsored the cause of medical reform the possibility that the profession will in the end refuse to take part in the N.H.S. is virtually buried, though concessions may be necessary before it commits itself. How these are to be secured from a Minister who has proved himself so stubborn in the past and believes he is going to be victorious ultimately is not stated.

The *British Medical Journal* on the other hand, having led us to believe (Panel Conferences, reports, etc.) that the Negotiating Committee had presented an unanswerable case, feels slightly hurt that the Minister made no conciliatory gesture by offering to make the smallest amendment of the Act. Much was made of Sections 35 and 36, but what does it all amount to when the Minister makes

it clear that if at a practitioner's expense a costly court case proves his interpretation of the sections wrong he would "take steps" to introduce legislation to restore his original intentions?

Two points occur here. The first is that no suggestion is given that the B.M.A. would or could bring a test case to relieve some practitioner of colossal expense; and the second, did the Negotiating Committee beg the Minister to omit *pro tem.* contentious clauses so that the Act could be operated in a "favourable atmosphere" and he made "the success which both they and he want it to be"? What we have in these documents is the presentation of two answers to the same problem—viz., can the N.H.S. be made to work well? The Minister says there are no difficulties about it given good will. The B.M.A. says no, it cannot, since the sacred principles are still violated.

As the *Daily Telegraph* said, the position is one of stalemate. Is it surprising that the practitioner is puzzled when one paper proclaims that this Act will make the medical profession the best paid in the country, while yet another informs us that to take in 4,000 units the doctor would have to be an athlete, a road hog, and as expeditious as lightning. One feels therefore that the Council of the B.M.A. should give us the inside facts to help us make up our minds. Surely the least we could expect is the immediate printing in the *Journal* of the verbatim account of the final discussions with the Minister. Did he present the velvet glove discernible in the Memorandum, or was the iron hand employed? Frankly, much of the difficulty arises because no one completely trusts Mr. Bevan—his intransigent attitude, his great powers under the Act, and his ability as a side-stepper are too well known. On the other hand, we should like to judge whether the Negotiating Committee properly presented their case. Only the fullest and early publication of what was said can enable the rank and file to instruct their Representatives at the S.R.M. on Jan. 8.

On closer examination of the documents no light is shed on (a) hours of work, (b) holidays, (c) provision of locums during unavoidable absence—e.g., sickness—(d) formation of a liaison body like the I.A.C. unless such is adumbrated by 26 (8). All these points are of importance before deciding what the remuneration amounts to.

Compensation.—Surely it is not the normal procedure in business when one party's interest in a business is acquired by another to defer payment till retirement or death. Did the Negotiating Committee press for a speedy payment of capital values so that the doctors could invest at better rates than 2½% if they so wished or could buy their own annuity or at least make it negotiable? What, for instance, would be the position of a doctor who is dismissed from a 95% service? Would his compensation and superannuation be paid or would they be forfeit? If the latter, the effect would be to make practitioners more subservient to an all-powerful Minister. On this matter of expulsion the *Lancet* naively suggests that we should be "saushed" with the Minister's proposal to set up an advisory committee instead of the right of appeal to the courts; "but only if members of the Service remain perpetually alert in the cause of professional freedom and ready to defend it at all levels. As with so much in this Service, the remedy here lies with ourselves." Is this a polite suggestion that, like the proletariat, we might stage a lightning strike occasionally? If doctors are not prepared now to insist on what the Panel Conference has already declared advisable, what possible chance is there of Ministerial puppets doing anything drastic?

Remuneration.—We should like to know how the figure of £300 basic salary was arrived at. With the sliding scales proposed it is very difficult to calculate what one's income would be. The unknown factors are (a) what proportion of the population would elect for panel doctoring, (b) the number of doctors who would either willingly or unwillingly take part. The figures (17,900) are misleading, as my information is that there are 21,000 general practitioners available plus 2,000 aliens who could come on the Register. If all these take part the capitation fee will fall badly. Here again one wonders if any attempt was made by the Negotiating Committee to get a fast rate fixed so that reasonable calculation could be made of one's expected income and help decide whether the N.H.S. offer was an economic proposition in each case.

Working things out on the figures given, this is what one urban practitioner's income might be, assuming a 95% service and a panel of 2,500. **Gross income:** £300+£1,895=£2,195. **Expenses** (approximate figures): Superannuation, £125; car (12 h.p., 12,000 miles yearly at 6d. per mile), £300; rental of surgeries, etc., £200; income tax on, say, £1,400 at average 8s. per £1, £560; rates on house, etc., £80. Total unavoidable practice expenses: £1,265. Net balance: £930.

With two children at school the position is not easy. If one child should wish to go to a medical school at, say, £360 per annum, it is quite impossible for another child to take up medicine as well. It would be a salutary measure if every medical practitioner would similarly work out his financial position from known expenses as for inland revenue returns.

Midwifery.—The position of the G.P. who sits in judgment on his colleagues' obstetrical ability is indeed an unenviable one. Why treat N. Ireland and Scotland differently from England and Wales in midwifery regulations?

Anethaine anaesthesia internationally accepted

'Anethaine' stood trial in the hardest of all proving grounds—the widely scattered theatres of war. Confirmation of its success is today's acknowledgment by medical men throughout the world that 'Anethaine' (amethocaine hydrochloride) is outstanding among local anaesthetics, high in activity and of relatively low toxicity.

Uses for 'Anethaine' are not restricted to major surgery. In ointment form it gives rapid relief from the minor pain and pruritus common to so many everyday accidents and affections—burns, haemorrhoids and insect stings, for instance. It is also valuable as an antiseptic lubricant in instrumental examinations, substantially reducing the discomfort to the patient. Of particular practical merit is the innocuous nature of 'Anethaine' Ointment; it may be safely prescribed for patients' personal application when desired.

THE FIRST YEAR OF LIFE

FOR SUCCESSFUL INFANT NUTRITION

At no other stage is the correct nutrition of the infant more important than in the first year of life. Breast feeding, if possible, remains the unchallenged method of laying this foundation of health. But if natural feeding fails, Cow & Gate Milk Foods provide a reliable and dependable substitute.

HALF CREAM

When foods other than breast milk are first introduced, some children require a reduced fat intake. In a smaller number of cases it is advisable to continue with the low fat content for several months. The half cream food, which contains the same vitamin and iron supplements as the full cream variety, has this reduction of fat with an addition of carbohydrate in the form of milk sugar.

FULL CREAM

This product conforms approximately to the fat content of average breast milk, and is prepared from finest quality milk powder made by the Cow & Gate Improved Roller Process, under scientifically controlled conditions. It contains 320 International Units Vitamin D and 1 milligram of iron per ounce.

COW & GATE MILK FOODS

Particulars of these and other Cow & Gate preparations for specialised infant feeding will be gladly forwarded on request.

the NEW analgesic...

First reports on the use of 'Physeptone' in general practice indicate that an outstanding advance has been made in the treatment of severe pain. With few exceptions, it may with advantage replace morphine, to which it is equal or superior in analgesic effect. 'Physeptone' does not unduly depress respiration, constipate, or induce narcosis or mental apathy; it may be given continuously for long periods without diminution of effect.

'Physeptone' is available in ampoules of 10 mgm. in 1 c.c. in boxes of 12 at 9/-, plus 2/3 purchase tax. For oral administration it is available as 'Tabloid' brand compressed products, 5 mgm., in bottles of 25 at 4/6, plus 1/1½ purchase tax, and bottles of 100 at 16/10, plus 4/2½ purchase tax (SUBJECT TO PROFESSIONAL DISCOUNT)

IMPORTANT: 'Physeptone' was brought under the Dangerous Drugs Act and Regulations on January 1st, 1948.

'PHYSEPTONE'

di-2-DIMETHYLAMINO-4:4-DIPHENYLHEPTANE-5-ONE HYDROCHLORIDE

BURROUGHS WELLCOME & CO.
(The Wellcome Foundation Ltd) LONDON

SIR.—We are not told how our contract, under which we are responsible for the treatment of patients on our panel list, is to be discharged when the State Medical Service comes into force. Under normal circumstances, a panel doctor remains responsible for the care of his patients until the expiration of three months' notice given at the beginning of a quarter. The doctor is fully bound otherwise, unless he arranges an approved deputy or transfer.

Does the National Health Service Act discharge the present contract by operation of law? It would be well to get this clear. Unless this is so, a panel doctor will, on July 1, 1948, be legally bound to attend, for a further three months, all patients then on his list, unless he has given notice of resignation to the Executive Committee not later than April 1, 1948. To give such notice on April 1, 1948, would be to deprive himself of the right to compensation in respect of his panel practice. He couldn't have a panel practice when the Act comes into force.

If the doctor did not give notice of resignation, and did not elect to practice under the Act, would it result, if an insufficient number of doctors joined the Service, in the panel doctor being compelled to attend to all or some of the patients then on his panel list, but being precluded from receiving remuneration out of public funds unless he enters into a new contract with the Minister?

As to the Act itself. May I take the opportunity of saying that, though not all doctors are in favour of the Act (and some of us are very much against the upheaval in the practice of medicine as we received it and have always known and regarded it), we must accept the fact that centralization and control are the ways of the world to-day. The Act is on the Statute Book. It would have needed a 100% vote against the Bill when it was going through Parliament to have defeated the only thing in it which really matters—that medical practices are to be taken over by the State after a given date. We were not sufficiently unanimous as a profession to oppose it. Time may prove that opposition was wrong. It may be that the relief from financial burdens and obligations that most G.P.s saddled themselves with will enable the young practitioner to keep his mind on his job and give him a longer and happier life.—I am, etc.,

H.C.

M. G. LUCAS.

SIR.—The Minister of Health's refusal to meet the profession in amending Sections 35 and 36 of the Act, despite the strong protest of the Negotiating Committee backed by prominent legal advice, is surely a very definite indication to the profession that there is a determination to enforce the Act as it stands ruthlessly, without any attempt to "meet any views of the profession which do not conflict with the principles of the Act." The unnecessary hardship likely to be inflicted—particularly on younger men in partnership with one of more advanced years where compulsory purchase of the retiring or deceased partner's share is a condition of the partnership agreement—is likely to impose a financial load of some considerable moment. The Minister's failure to concede what to him must be a minor point must cause much misgiving when we realize the powers he is determined to assume in other directions over the life and soul of the profession from "the appointed day."

The suggestion is made that the continuance of partnerships or group practice is desirable, and most of us will agree with this; but once again one of the main safeguards of the patient of such a partnership has been that the choice of a new partner has been made by the partnership. Under the new Act no mention is made of any participation in the selection of the new partner by the existing partners, unless they happen to be members of the Medical Practices Committee; and I am convinced that, unless this is remedied, group practice such as we understand it at present will be eliminated through natural causes in course of time, as no one would be such a fool as to risk the choice of an independent body without accurate knowledge of the personalities in existing partnerships.

The basic salary might well be confined to that offered by the Executive Council through the Medical Practices Committee to the nominee to a vacancy in a partnership practice during a, say, six- or twelve-months preliminary assistantship such as is undertaken at present, to determine (1) whether the partners approve, and—Mr. Bevan please note—(2) whether the patients can cope with the incomer. At the end of that time the new partner would be sufficiently well known to create his own practice and income, whether by purchase and share in the general income or by gradual acquisition of overflow from the existing practitioners.

Most of us accept without hesitation the idea of a "General Medical Service for the Nation," but, quite apart from personal or, shall I say, selfish grounds, we are in a prime position to anticipate the effect on the patient of the implementation of the National Health Service Act as it stands. It is a great pity that we are not doing more to make the general public realize the inevitable deterioration which must ensue in the type of service which must be the outcome of Mr. Bevan's obstinate determination to drive us into a full-time State salaried service, where our allegiance would be to our new employer—the State—and not to our present employer—the patient.—I am, etc.,

Bishop's Stortford, Herts.

R. P. GAMMIE.

SIR.—In the last ballot I answered "Yes." Had the issue been explained in more definite and concise language I should have answered "No." The official communications—(1) the Negotiating Committee's case, (2) the Minister's reply—published in the *Journal* of Dec. 20 (pp. 141 and 154) are again not sufficiently clear and may lead to confusion in the forthcoming ballot. I feel sure that a concise and simple summary of the whole position such as appeared in the *Daily Telegraph* of Dec. 22 by Mr. Derek Walker-Smith, M.P., is required.

It is certain that medical dictatorship will gradually replace medical democracy if we accept the Act in its present form. I therefore consider it essential that (1) a more detailed plan than has already been done be published for the guidance of all doctors who decide to stay outside the scheme—i.e., collection of fees, etc.; (2) the date of the ballot be postponed several weeks until the whole profession is properly organized to give battle should such be necessary.

The new National Health Service should not be accepted until the Act has been changed to recognize the following five main points:

(1) The right of appeal to the courts against dismissal by the Minister.

(2) Payment by capitation fee only. The basic salary should not be accepted, as it is only the thin end of the wedge towards a full-time salaried State service.

(3) Freedom of any doctor to practise anywhere. The amount of practice available by means of the capitation fee will act as a self-limiting factor, as under the present system. The stimulus to practise in unattractive areas should be by means of an increased capitation fee only.

(4) A clear definition of what constitutes a nursing-home. Anything that falls under this category should not be taken over by the State. Unless this is guaranteed the so-called freedom to remain outside the Service becomes a joke. Unless assured of the existence of private nursing-homes general practitioners and specialists who remain outside the Service are likely to find themselves without any facilities to treat patients suffering from anything other than minor ailments.

(5) Freedom of all doctors in any State service including the fighting Services (in peacetime) to publish anything they wish in any of the recognized medical journals without permission of their respective Service and without censorship other than that of the particular medical journal in question.—I am, etc.,

SERVICE PRACTITIONER.

SIR.—There is one point in the Minister's reply which I have not yet seen mentioned, but which is of great importance to the majority of general practitioners.

The Minister says: "There is no suggestion, of course, that any qualified medical practitioner should be in any way debarred from practising midwifery." Then later he says: "This committee will decide on the list of local practitioners suitable for answering calls from midwives and at the same time taking part in the maternity services provided by the new Act. Others, not included in the list, will need further obstetrical experience first, and the list will be periodically reviewed." How in the name of reason can these statements be reconciled?

If I am one of the "others" will I, or will I not, be debarred from practising midwifery in the Service? Or, to be even more specific, if I am in the Service but not elected to the midwifery list will I be able to take medical charge and responsibility for the prenatal and post-natal care and the confinement of my insured patients, and be paid for these services by

their work, and they usually disappear, but the nutritional upset persists, and under the influence of lymph stasis the papilloma may ultimately in the course of years evolve into carcinoma without the intervention of any new factor.

In lupus cancer, x-ray cancer, and tongue cancer I have traced every stage of this process, and Mr. O'Connor will find the evidence fully stated in my book *The Genesis of Cancer* (Kegan Paul, London, 1931). I have not had the material for extending my observations to cancer of the penis and of the cervix, but it seems most unlikely that these forms of cancer are exceptions to a rule which appears to be general. The papilla is a little physiological engine. It must be supplied with not too rich a mixture at the right pressure, and must have a free exhaust. Lymph stasis following local bacterial infection violates all these conditions, and cancer is the ultimate consequence.

Temporary lymph stasis is seen in every focus of acute inflammation as Nature's method of inducing proliferation and repair. The enormous legs of elephantiasis show how intense is the proliferative impulse imparted to a tissue if the lymph stasis is permanent. It was from a case of elephantiasis which presented about fifteen separate epitheliomata on the affected limb that my researches started.—I am, etc.,

London, W.1.

W. SAMPSON HANDLEY.

A Method of Abdominal Palpation

SIR,—Dr. E. W. Price (Nov. 1, 1947, p. 703) argues in favour of abdominal palpation when the patient is sitting upright or leaning forward. I have been convinced for a long time that the abdominal palpation used on patients supine is frequently insufficient, and so I complete this first examination, when necessary, by the following methods:

(1) *Genu-cubital Position*.—This throws forward the deeper organs and enables one to distinguish some pains, especially those issuing from the right iliac fossa.

(2) *Orthostatic Position*.—When the patient leans forward, or is sitting, his legs are drawn up against his abdomen. Therefore I usually ask the patient to *lean backwards* and relax as much as he can. In order to make this possible he must be supported at the back. The physician behind the patient could support him, but this situation might prove awkward in some instances.

In order to avoid this difficulty I have had a "palpation board" constructed. It is 14 in. (35.6 cm.) wide and 6 ft. (1.83 m.) high. The top part of the board is attached to the wall at a distance of 17 in. (43.2 cm.), while the base of it is 24 in. (61 cm.) away; this inclines the board at an angle of 8–10 degrees.

To use the vertical palpation, one stands behind the board, between it and the wall. The patient is standing against the board in a leaning position and completely relaxed. The top part of the board is adapted with a groove; this enables it, when not in use, to be slid back against the wall so as not to take up too much room.—I am, etc.,

General Anaesthesia and Surgical Shock

SIR,—In a recent article (1947) I cited evidence to prove that fainting and shock are identical in origin, and that both are due to overstimulation of the sympathetic nervous system, a prominent cause of which in civilized man is pain. Opponents of the theory of the sympathetic origin of shock have pointed out that shock fails to develop in conditions such as biliary and renal colic, in which pain is intense and prolonged (Moon, 1938). Painful (sensory) impulses, however, are not the only shock-producing impulses arising in damaged tissues (Moon, 1944).

That pain is capable of causing shock is clearly demonstrated by the effect, in pre-antiseptic days, of the introduction of general anaesthesia on the mortality from surgical operations (amputations). It is to be remembered that general anaesthesia, though effectively cutting off all painful impulses from the vasomotor centre via the sensorium, does not prevent the reception by that centre of non-sensory shock-producing impulses from the traumatized area via the spinal cord. To prevent the reception of such impulses spinal anaesthesia is required (Tomb, 1937).

In an address to the Hunterian Society in 1848 "On the Advantages of Ether and Chloroform in Operative Surgery" Dr. T. B. Curling quoted statistics showing that the death rate from surgical operations in the London hospitals during the year 1847–8 fell by 50% consequent upon the introduction of general anaesthesia—a result which must be attributed to the diminution of shock from the prevention of pain and the sympathetic overstimulation arising therefrom.—I am, etc.,

Sydney.

Thiouracil in Toxic Goitre

SIR,—In his letter (Dec. 6, 1947, p. 927) in connexion with our paper on "Thiouracil in Toxic Goitre" (Nov. 15, p. 759) Mr. Henri Ronalle mentions experiments in which thyroid tumours have been produced in rats treated with thiourea. Although these and previous experiments on the same lines are remote from the clinical use of thiouracil, a watch must be kept for neoplasm developing in the thyroid in patients taking thiouracil. After four years' experience we have not yet seen such a development nor has it been reported as far as we know. In the animal experiments the thyroid enlarges, whereas in our experience thiouracil often leads to a reduction in the size of the goitre.

Mr. Geoffrey Keynes and Dr. J. W. Linnell (Dec. 13, p. 971) think that the ten deaths in our 95 patients are to be attributed to thiouracil or perhaps failure to employ some other form of treatment. In nine of the ten this was not so, as shown by the details we gave. Three cases were too near death on arrival for any treatment to be effective; they had thiouracil for a few days to a few weeks before death. Six patients died from cardiovascular disease not immediately due to toxic goitre. The average age of these nine patients who died was 70 years.

As to the potency of thiouracil in restoring normal rhythm in goitrous fibrillation, our figure of 50% restored understated the case. This was because we included in the failures two patients who died shortly after coming under observation and before there was time for thiouracil to exert its effect, and also one, possibly two, patients who also had mitral stenosis. No quinidine was used for any patient. It therefore seems that thiouracil is almost the equal of thyroidectomy in converting goitrous fibrillation to normal rhythm. Lastly, as to the cases in which thiouracil is to be preferred to surgery in toxic goitre, we think that this applies to the elderly, thiouracil being the safer, particularly in those with evidence of degenerative or hypertensive cardiovascular disease. Again, in younger patients with smooth goitres of moderate or small size our results showed good control with thiouracil and a high proportion of remissions.—We are, etc.,

Tetraethylammonium Bromide

SIR,—In the annotation (Dec. 27, 1947, p. 1041) attention is drawn to the great possibilities of the drug tetraethylammonium bromide (T.E.A.B.). Stimulated by the early American publications, we obtained supplies of this drug early this year for clinical trial through the kindness of Dr. W. R. Thrower and Messrs. May and Baker. A short paper is being prepared giving the results of this trial, but it is not out of place to remark here that we have in general failed to produce the very favourable results reported by Collier *et al.* last June (*Annals of Surgery*, 1947, 125, 729).

Our main use of the drug was to attempt to reduce those symptoms most troublesome to hypertensives attending the medical out-patient department—i.e., headaches and giddiness—by weekly or fortnightly administration of T.E.A.B. intravenously or intramuscularly. We found that some patients obtained dramatic benefit, headaches disappearing for days or even weeks and vision clearing appreciably, so that the smaller newspaper previously unreadable could be read with comparative ease. This last statement was made quite independently by three separate out-patients who had never seen each other and to whom no suggestion had been made that improvement

the State, or will I have to send my patients to a midwife and another doctor on the "list"? Can the Minister or anyone interested in seeing this part of the Act implemented as it stands to-day tell us the answer to these questions?

The matter seems to me to strike at the very root of our acknowledged principle of being free to exercise the art and science of medicine.

If the "others" are debarred from practising midwifery in the Service, then the first sentence quoted can, at best, only be called a terminological inexactitude. The "others" have been passed as competent by their university or college professors or they would not be qualified, and in the absence of proved incompetence or negligence after qualification I can see no justification whatever for preventing them working in the Service. General practitioners might next be prevented from treating pneumonia as this would be the province of "physicians," from treating a whitlow as this would be the province of a "surgeon," from giving an anaesthetic as this would be the province of an "anaesthetist."

We are qualified practitioners. It has been and should continue to be our right to decide when we shall refer our patients to another practitioner. And that should be only when we feel in need of his help or advice—and not when we are instructed to do so from "higher authority."

My fears are not fancies. Many of us experienced interference in our professional freedom during the war, but that is not necessary now. Let us see that it shall not be so by our united voice. In this as in the other vital issues raised with the Minister it is only by unity that we can ensure that the best possible service is evolved for our patients and ourselves.—I am, etc.,

Harrogate.

D. C. WILLIAMS.

SIR,—A crucial question at this time which I think is being forgotten is, Do the public gain in health through the introduction of the Service at this stage?

The answer is obviously "No." The Service will call for more work among doctors owing to more visits by patients and the inevitable form-filling which is the necessary evil of any co-ordinated service. If we look upon the patients as the material with which we work, and whose medical well-being is our "finished job," then I'm afraid we're being forced on them at a time when workmen and material are of poor quality. We should have workshops (hospital beds)—the present numbers are inadequate; also assistants (nurses)—whose number is also inadequate.

A little variation in available foods may brighten a few in mind if not in body. Tuberculous-infected milk can still take its toll of children, and tuberculous patients still linger at home waiting for hospital beds. However bad these are, and however good are the excuses for not remedying them now, the introduction of a health service, which to the patient promises improvement in medical care, can do nothing—in fact, we could be made the scapegoat for its failure.

Let us accept the role of heaven-sent advisers to Aneurin Bevan and tell him gently "No," or at least "Not yet."—I am, etc.,

Newport, Mon.

H. J. HOUGHTON.

SIR,—I have never seen or heard discussed the obvious solution to the aim of the National Health Service—the desire of the public for the avoidance of doctors' bills. All patients desire private (in every sense) service, and pay for such when possible. Why not have universal private practice, raising panel patients to the private level, and let the £66 millions, plus insurance, pay the doctors' bills?—I am, etc.,

Farnham, Kent.

H. M. DENHOLM-YOUNG.

SIR,—In all the letters which you publish in your issue of Jan. 3 I have not observed any mention of the one solid ground upon which we may rightly take our stand with the solid psychological backing of the general public, a prerequisite to any success—i.e., the absence of the right of appeal to the High Court. No amount of "haggling" over fees or the precise method of remuneration would cut much ice with the public, enlist their sympathy, or enhance our prestige. But to refuse

us a right of appeal is a refusal of bare justice and reason, weakens the Minister's case, and is clearly illogical. *The Times* leader complained that the dispute was passing from the logical into the emotional. No emotion is involved in the right of appeal. I am heartily in favour of a basic salary.—I am, etc.,

Hassocks, Sussex.

CHARLES FRANKLYN.

SIR,—One hears the question asked, "What can we do if the Minister brings the Act into operation in spite of us?" with dark hints as to the penalties for strikes by bodies other than trade unions. Surely there can be no question of a strike against a non-existent employer? Again, is there anything to prevent the individual general practitioner from saying to a patient on and after July 5, "I am not in the Service. I am perfectly willing to treat you, but in case the Minister gets up to any hanky-panky about the recovery of medical fees I must ask you to pay me each time I see you, and I am sorry, but I cannot let you have any certificate for anything." Perhaps some of your readers learned in the law will let us have their views on our powers and limitations.—I am, etc.,

Launceston, Cornwall.

DONALD M. O'CONNOR.

The Treatment of Myasthenia Gravis

SIR,—Your interesting annotation on this subject (Dec. 13, 1947, p. 966) did not mention the recent work of Torda and Wolff (*Arch. intern. Med.*, 1947, 80, 68) on the effect of intravenous administration of an enzymic hydrolysate of casein ("amigen") to five cases of myasthenia gravis. The concept that much of the symptomatology of myasthenia gravis could be explained by decreased synthesis of acetylcholine, and the demonstration that this synthesis could be increased *in vitro* by amino-acids and proteins, provided the rationale for their procedure. Muscle action potential records were made in patients with myasthenia gravis and in healthy subjects. Full details are given of one patient in whom the known decline of the amplitude of muscle action potential after prolonged indirect stimulation was prevented by amigen; this patient was even able to postpone the taking of "neostigmine bromide." The remaining cases were less severe, but responded similarly. There was an improvement in muscle function signified by increased performance of work and a reduction in the daily requirement of neostigmine bromide during the period of amigen administration. Obviously this effect of amino-acids in myasthenia gravis may implicate many processes, and examples of these are discussed. Admittedly Torda and Wolff stated that "no therapeutic implications are justifiable from these preliminary experiments," but their apparently favourable results would seem to deserve notice.—I am, etc.,

Rowett Research Institute, Aberdeen.

Penile Carcinoma

SIR,—I am bound to meet the friendly challenge of Mr. D. M. O'Connor (Dec. 20, 1947, p. 1010) for evidence of my belief that the mixed bacterial flora rampant beneath the phimotic prepuce may be transferred to the vagina and may there set up cervical carcinoma. The admitted relative freedom of Jewish women from the disease already raises a presumption in favour of this explanation.

For many years I sought to find a specific peculiarity in the tissues of precancerous areas. Such areas have usually been the sites of chronic local infection, especially by the staphylococcus, the treponema, the tubercle bacillus, or by a virus, or have been subjected to the action of tar or other chemicals; or have been unduly exposed to solar or x-ray radiation. Anatomically, on skin surfaces the cancer is preceded by papillary hypertrophy, on mucous surfaces by the formation of adenomata. I have demonstrated that a lymphatic capillary is the central structure of each papilla of the skin, and that in a papilloma this central lymphatic is blocked by previous infective lymphangitis. This observation, simple as it is, is in my opinion the key to the origin of cancer. A rise in intercellular pressure necessarily follows, the papilla swells up, and all its tissues are nourished at high pressure by stagnant but over-rich tissue fluid, largely deprived of its hormones and probably poor in oxygen. At this stage the bacteria have done

the State, or will I have to send my patients to a midwife and another doctor on the "list"? Can the Minister or anyone interested in seeing this part of the Act implemented as it stands to-day tell us the answer to these questions?

Penile Carcinoma

SIR,—I am bound to meet the friendly challenge of Mr. D. M. O'Connor (Dec. 20, 1947, p. 1010) for evidence of my belief that the mixed bacterial flora rampant beneath the phimotic prepuce may be transferred to the vagina and may there set up cervical carcinoma. The admitted relative freedom of Jewish women from the disease already raises a presumption in favour of this explanation.

For many years I sought to find a specific peculiarity in the tissues of precancerous areas. Such areas have usually been the sites of chronic local infection, especially by the staphylococcus, the treponema, the tubercle bacillus, or by a virus, or have been subjected to the action of tar or other chemicals, or have been unduly exposed to solar or x-ray radiation. Anatomically, on skin surfaces the cancer is preceded by papillary hypertrophy, on mucous surfaces by the formation of adenomata. I have demonstrated that a lymphatic capillary is the central structure of each papilla of the skin, and that in a papilloma this central lymphatic is blocked by previous infective lymphangitis. This observation, simple as it is, is in my opinion the key to the origin of cancer. A rise in intercellular pressure necessarily follows, the papilla swells up, and all its tissues are nourished at high pressure by stagnant but over-rich tissue fluid, largely deprived of its hormones and probably poor in oxygen. At this stage the bacteria have done

their work, and they usually disappear, but the nutritional upset persists, and under the influence of lymph stasis the papilloma may ultimately in the course of years evolve into carcinoma without the intervention of any new factor.

In lupus cancer, x-ray cancer, and tongue cancer I have traced every stage of this process, and Mr. O'Connor will find the evidence fully stated in my book *The Genesis of Cancer* (Kegan Paul, London, 1931). I have not had the material for extending my observations to cancer of the penis and of the cervix, but it seems most unlikely that these forms of cancer are exceptions to a rule which appears to be general. The papilla is a little physiological engine. It must be supplied with not too rich a mixture at the right pressure, and must have a free exhaust. Lymph stasis following local bacterial infection violates all these conditions, and cancer is the ultimate consequence.

Temporary lymph stasis is seen in every focus of acute inflammation as Nature's method of inducing proliferation and repair. The enormous legs of elephantiasis show how intense is the proliferative impulse imparted to a tissue if the lymph stasis is permanent. It was from a case of elephantiasis which presented about fifteen separate epitheliomata on the affected limb that my researches started.—I am, etc.,

London, W.1.

W. SAMPSON HANDLEY.

A Method of Abdominal Palpation

SIR,—Dr. E. W. Price (Nov. 1, 1947, p. 703) argues in favour of abdominal palpation when the patient is sitting upright or leaning forward. I have been convinced for a long time that the abdominal palpation used on patients supine is frequently insufficient, and so I complete this first examination, when necessary, by the following methods:

(1) *Genucubital Position*.—This throws forward the deeper organs and enables one to distinguish some pains, especially those issuing from the right iliac fossa.

(2) *Orthostatic Position*.—When the patient leans forward, or is sitting, his legs are drawn up against his abdomen. Therefore I usually ask the patient to *lean backwards* and relax as much as he can. In order to make this possible he must be supported at the back. The physician behind the patient could support him, but this situation might prove awkward in some instances.

In order to avoid this difficulty I have had a "palpation board" constructed. It is 14 in. (35.6 cm.) wide and 6 ft. (1.83 m.) high. The top part of the board is attached to the wall at a distance of 17 in. (43.2 cm.), while the base of it is 24 in. (61 cm.) away; this inclines the board at an angle of 8-10 degrees.

To use the vertical palpation, one stands behind the board, between it and the wall. The patient is standing against the board in a leaning position and completely relaxed. The top part of the board is adapted with a groove; this enables it, when not in use, to be slid back against the wall so as not to take up too much room.—I am, etc.,

Geneva

M. J. DEMOLE.

General Anaesthesia and Surgical Shock

SIR,—In a recent article (1947) I cited evidence to prove that fainting and shock are identical in origin, and that both are due to overstimulation of the sympathetic nervous system, a prominent cause of which in civilized man is pain. Opponents of the theory of the sympathetic origin of shock have pointed out that shock fails to develop in conditions such as biliary and renal colic, in which pain is intense and prolonged (Moon, 1938). Painful (sensory) impulses, however, are not the only shock-producing impulses arising in damaged tissues (Moon, 1944).

That pain is capable of causing shock is clearly demonstrated by the effect, in pre-antiseptic days, of the introduction of general anaesthesia on the mortality from surgical operations (amputations). It is to be remembered that general anaesthesia, though effectively cutting off all painful impulses from the vasomotor centre via the sensorium, does not prevent the reception by that centre of non-sensory shock-producing impulses from the traumatized area via the spinal cord. To prevent the reception of such impulses spinal anaesthesia is required (Tomb, 1937).

In an address to the Hunterian Society in 1848 "On the Advantages of Ether and Chloroform in Operative Surgery" Dr. T. B. Curling quoted statistics showing that the death rate from surgical operations in the London hospitals during the year 1847-8 fell by 50% consequent upon the introduction of general anaesthesia—a result which must be attributed to the diminution of shock from the prevention of pain and the sympathetic overstimulation arising therefrom.—I am, etc.,

Sydney.

Thiouracil in Toxic Goitre

SIR,—In his letter (Dec. 6, 1947, p. 927) in connexion with our paper on "Thiouracil in Toxic Goitre" (Nov. 15, p. 759) Mr. Henri Roualle mentions experiments in which thyroid tumours have been produced in rats treated with thiouracil. Although these and previous experiments on the same lines are remote from the clinical use of thiouracil, a watch must be kept for neoplasm developing in the thyroid in patients taking thiouracil. After four years' experience we have not yet seen such a development nor has it been reported as far as we know. In the animal experiments the thyroid enlarges, whereas in our experience thiouracil often leads to a reduction in the size of the goitre.

Mr. Geoffrey Keynes and Dr. J. W. Lionell (Dec. 13, p. 971) think that the ten deaths in our 95 patients are to be attributed to thiouracil or perhaps failure to employ some other form of treatment. In nine of the ten this was not so, as shown by the details we gave. Three cases were too near death on arrival for any treatment to be effective; they had thiouracil for a few days to a few weeks before death. Six patients died from cardiovascular disease not immediately due to toxic goitre. The average age of these nine patients who died was 70 years.

As to the potency of thiouracil in restoring normal rhythm in goitrous fibrillation, our figure of 50% restored understated the case. This was because we included in the failures two patients who died shortly after coming under observation and before there was time for thiouracil to exert its effect, and also one, possibly two, patients who also had mitral stenosis. No quinidine was used for any patient. It therefore seems that thiouracil is almost the equal of thyroidectomy in converting goitrous fibrillation to normal rhythm. Lastly, as to the cases in which thiouracil is to be preferred to surgery in toxic goitre, we think that this applies to the elderly, thiouracil being the safer, particularly in those with evidence of degenerative or hypertensive cardiovascular disease. Again, in younger patients with smooth goitres of moderate or small size our results showed good control with thiouracil and a high proportion of remissions.—We are, etc.,

Tetraethylammonium Bromide

SIR,—In the annotation (Dec. 27, 1947, p. 1041) attention is drawn to the great possibilities of the drug tetraethylammonium bromide (T.E.A.B.). Stimulated by the early American publications, we obtained supplies of this drug early this year for clinical trial through the kindness of Dr. W. R. Thrower and Messrs. May and Baker. A short paper is being prepared giving the results of this trial, but it is not out of place to remark here that we have in general failed to produce the very favourable results reported by Coller *et al.* last June (*Annals of Surgery*, 1947, 125, 729).

Our main use of the drug was to attempt to reduce those symptoms most troublesome to hypertensives attending the medical out-patient department—i.e., headaches and giddiness—by weekly or fortnightly administration of T.E.A.B. intravenously or intramuscularly. We found that some patients obtained dramatic benefit, headaches disappearing for days or even weeks and vision clearing appreciably, so that the smaller newspaper previously unreadable could be read with comparative ease. This last statement was made quite independently by three separate out-patients who had never seen each other and to whom no suggestion had been made that improvement

in visual acuity would result. The easing or abolition of headache for as long as several days surprised us, as the effect of the drug on the blood pressure is short-lived, lasting from a few minutes to at most an hour or two. We therefore substituted control injections of saline, elaborate and lengthy readings of blood pressure being taken as before, retinæ and pupils being examined every few minutes. Equally satisfactory results in improvement in vision and lessening of headache were reported by the patients after such "dummy" injections.

Apart from this small group where improvement was effected by suggestion no really satisfactory results were obtained with the drug, and the high hopes we held for its being useful in treatment of hypertensive patients unsuitable for sympathectomy have not been fulfilled. We have found the effect of the drug on skin temperature of the extremities variable and erratic and less satisfactory than simpler methods. In some cases, little or no drop in blood pressure resulted, though most patients had some depression of systolic and diastolic pressure for 3 to 30 minutes after intravenous injection of 100-600 mg. of the drug. The rate of the injection appeared to play a part as well as the dosage given, the more rapid the administration of the drug the more the effect on the blood pressure.

As stated in your annotation, T.E.A.B. is an impracticable therapeutic agent, but it may prove of use to the research worker. We have not found it a useful drug either in testing rises in peripheral skin temperature or in lessening symptoms in hypertensive subjects. In the last group of cases the psychogenic element features largely in so many cases, and it is easy to produce symptomatic relief by suggestion backed by elaborate investigation. Nevertheless it is possible that new uses may yet be found for this drug, and our trial is still in progress.—I am, etc.,

London, S.W.1.

F. DUDLEY HART.

Acute Non-specific Gastro-enteritis

SIR,—We note with interest the letter from Dr. William Forster (Dec. 13, 1947, p. 971) describing an outbreak of acute non-specific gastro-enteritis in a mental hospital, and we would like to comment on a few of the points made in it.

Treatment and Prophylaxis with Sulphonamide Drugs.—In our experience of a number of outbreaks, some in mental hospitals, treatment of established cases of gastro-enteritis of this type with sulphaguanidine has been without effect on the duration and severity of illness as compared with controls treated symptomatically, a finding in agreement with that obtained by Dr. Forster, using phthalylsulphathiazole. Dr. Forster suggests, however, that "sulphonamides were effective in prophylaxis." Examination of the data given in his letter yields little to support this conclusion, for the drugs were administered when the ward outbreaks had been in progress for some days (9-17 days) and when the attack rates were declining naturally. Again, at least four patients commenced the disease while they were actually receiving prophylactic sulphonamide.

In our experience the duration of outbreaks in mental-hospital wards where no prophylaxis had been undertaken was relatively short, due possibly to the rapid spread of the disease through an unchanging population. Thus in a Leicester mental-hospital outbreak¹ the duration of ward outbreaks on the male side of the hospital ranged from 7 to 14 days (mean 9.8 days) and on the female side from 12 to 22 days (mean 18.4 days). There was therefore considerable variation between wards, but the figures are of the same order as those (12, 15, and 20 days) occurring in Dr. Forster's wards in which prophylaxis was undertaken. The variability between untreated wards makes deductions concerning the value of prophylactic treatment extremely hazardous.

Variation in Attack Rates in Wards with Different Populations.—It was very interesting to note the uniform gradation of the size of attack rate in different wards as given in the table of Dr. Forster's letter. Thus, wards having overcrowded low-grade mental patients tended to have higher attack rates than the wards which were less crowded and had patients of a higher mental grade. We have observed a similar gradation in two mental-hospital outbreaks.² This may be partly a reflection of the degree of day-time dispersion in different ward populations, but investigation of these differences and their relation to the mode of spread of the disease might be illuminating. The problem might be approached by comparing the attack rates in "non-specific gastro-enteritis" in these varying ward populations with the rates observed on the one hand in diseases whose method of spread is intestinal-oral, such as bacillary dysentery, or on the other hand "airborne," such as influenza.

Mode of Spread of the Disease.—In the mental-hospital outbreaks that we have investigated, as in that investigated by Dr. Forster,

case-to-case infection rather than water or massive food-borne infection has been the pattern of spread. Dr. Forster states, however, that the infection was "probably airborne" in his outbreak. It would be interesting to know the facts which led Dr. Forster to this conclusion. It is a commonly held belief that the disease is spread by the "airborne" route, but we are in ignorance of the epidemiological method which enables a distinction to be made between "airborne" and case-to-case contact spread of infection. The mere fact that the disease is very infectious, has high attack rates and a particular seasonal incidence, is not by itself sufficient evidence for a respiratory mode of spread.

The findings of Reimann *et al.*,³ who transmitted a similar gastro-enteritis to student volunteers when they inhaled nebulized filtrates of throat washings or stool but failed to infect volunteers by feeding stool filtrate, have influenced the interpretation of outbreaks in this country. Reimann was, however, the first to point out that his experiments were undertaken under difficult circumstances in that the volunteers could not be isolated from the rest of the student body which was experiencing natural attacks of the disease. Further, examination of his figures reveals that the incubation period was between 9 and 21 days in 42% of the volunteers having gastro-enteritis, and as the natural incubation period is 3-5 days it is questionable whether these later cases were in fact due to inoculation. The volunteers were inoculated in batches on six different days using, from (presumably) different donor material which consequently may have been of different activity. The results obtained by Reimann should, therefore, be applied with caution until they have been confirmed.

Recently a well-planned and controlled experiment has been undertaken in New York by Gordon and colleagues.⁴ These investigators, using known susceptible and carefully isolated volunteers, have shown that a clinically similar gastro-enteritis of the type under discussion can be transmitted by ingestion of filtered stool or unfiltered throat washings but not by the inhalation of nebulized throat washings known to be infective by ingestion. It remains to be proved, of course, that the disease described by Reimann, the New York workers, and various investigators in this country is in fact the same regardless of the similarity of clinical picture, but enough has been said to illustrate the need for caution in labelling the disease an "airborne" infection.—We are, etc.,

Penicillin in Otitis Media

SIR,—With reference to the report of the meeting of the Section of Otolaryngology of the Royal Society of Medicine (Dec. 27, 1947, p. 1049) may I be permitted to give a general practitioner's experience in the treatment of otitis media with systemic penicillin, both in acute and chronic cases?

I use the oil-wax suspension of 1,250,000 units in 10 ml., giving a single injection of 200,000 to 300,000 units daily. I had eleven cases of acute otitis media with otorrhoea in children between the ages of 2 and 14, and, with the exception of one, there were no recurrences from two to eight months after injection. The discharge ceased on the second or third day and hearing became normal within fourteen days. I gave another course of penicillin to the recurrent case, and the patient has been free from discharge for the last four months. I have also dealt with six cases of otorrhoea due to chronic otitis media, out of which three recurred, the other three having now been free from discharge from eight to thirteen months. One of the recurrent cases had another course of penicillin injections and has now been free from discharge for the last four months.

I give herewith a short history of a case of chronic otitis media:

A man aged 44 developed a right otitis media with otorrhoea 36 years ago. He had been attending hospital ever since and was treated with peroxide ear drops. He was never free from aural discharge for more than two months. His hearing was becoming impaired and he felt dizzy on bending down his head. In November, 1946, I gave him one injection daily of 250,000 units of penicillin calcium in oil-wax suspension for five days. The discharge ceased on the third

day, his dizziness disappeared in a week, and after more than thirteen months the discharge has not recurred, his hearing is greatly improved, and his dizziness has ceased.

I write in order to refute the claim that four-hourly injections are necessary, as stated by Mr. I. Simson Hall (Dec. 27, 1947, p. 1050), and also to make a strong appeal to other doctors to try treating the chronic cases of otitis media with large doses of penicillin, as suggested above, since the number of cases of otitis media in the country must be enormous, and apart from the inconvenience of discharging ears and deafness there is always a danger of more serious complications. Operation, apart from its risk, is not always effective, and patients are usually reluctant to submit to it.—I am, etc.,

Sheffield, 5.

I. GOTTLIEB.

Dicoumarol

SIR,—From the vast literature on the pharmacological action and therapeutic use of dicoumarol there appear several findings which are of importance in the control of dicoumarol therapy: (a) It is not advisable to reduce the prothrombin to such a degree that the ordinary blood-clotting time becomes prolonged.¹ (b) Very low prothrombin concentrations must be attained before the clotting time is significantly altered.² (c) Intravascular thrombosis rarely occurs in patients on dicoumarol if the prothrombin is kept below 30%, while haemorrhagic complications are rare if the prothrombin is kept above 10%.³ (d) In the Quick method of prothrombin estimation the source of thromboplastin is acetone-dried rabbit brain.^{4,5}

The clotting time (Lee and White method), which Dr. M. J. Pivawer (Dec. 6, 1947, p. 928) recommends as a means of controlling the dosage of dicoumarol, has very little experimental evidence to support it. From my own experience the clotting time does not appear to give sufficient warning of the approach of, nor in some cases the arrival at, the danger level of 10% prothrombin. This is illustrated in the following case.

Case 1.—A post-operative patient received 650 mg. dicoumarol over a period of three days. On the fourth day the prothrombin concentration was found to be less than 10% by the Quick method and 35% by the Fullerton modification⁶ of the Quick method. The patient developed a haematoma at the site of operation. At this stage the clotting time (Lee and White method) was normal and no different from the clotting time estimated before the administration of dicoumarol.

Full details of Quick's method are to be found in his excellent monograph. I have found acetone-dried human brain to give as satisfactory results as acetone-dried rabbit brain. For every batch of dried brain which one obtains a graph must be plotted correlating prothrombin times with prothrombin concentrations. In the Fullerton modification⁶ of the Quick method Russell-viper venom is the source of thromboplastin. The results are often misleading and may cause an overdosage with dicoumarol. This is illustrated by the following case.

Case 2.—A post-operative case which developed a thrombophlebitis received 1,700 mg. of dicoumarol over a period of eight days. Prothrombin estimations were carried out daily by the Fullerton modification. At no time during the eight days was the prothrombin found to be below 25%, which, in view of the large amount of drug administered, was rather curious. On the eighth day I estimated the prothrombin by both methods. The prothrombin was well below 10% by Quick's method and about 25% by the Fullerton modification. Treatment with dicoumarol was immediately stopped, but the prothrombin concentration continued to fall. Six days later the patient had a severe epistaxis, and it was noticed that his operation scar was not healing. At this stage the prothrombin was less than 5% (Quick method) and about 20% (Fullerton modification). Fortunately in this case the prothrombin began to increase the next day and bleeding stopped. About six days elapsed before the prothrombin was over 30%.

Dr. Frank Marsh (Dec. 20, 1947, p. 1009) advocates a method in which "perfectly fresh viper venom of (if possible) guaranteed potency" is required. This method, in which "it may be necessary to do twelve tests on one specimen of plasma," seems to me to be complicating the issue. With the Quick method the results are so concordant that it is rarely necessary to use more than three tubes per specimen of plasma.

My conclusions are, therefore, that the most reliable method at present for the control of dicoumarol therapy is the daily

estimation of prothrombin concentration (sometimes called prothrombin activity) by means of Quick's method, in which the source of thromboplastin is acetone-dried brain. Using this method I find that 24 hours after the administration of 300 mg. dicoumarol the majority of cases show a prothrombin concentration of 50% or lower. It is these latter figures which determine the dose to be given on the second day. Most workers will agree with your correspondents that heparin is most valuable, in certain cases, during the period when dicoumarol has not yet lowered the prothrombin concentration to the optimum range of 10 to 30%.—I am, etc.,

Manchester.

SIR,—We have been interested in the increasing correspondence regarding the administration of dicoumarol and feel that the letter of Dr. M. J. Pivawer (Dec. 6, 1947, p. 928) calls for critical comment. First, in our experience Quick's method of prothrombin-time estimation has given satisfactory results. There are one or two practical points which are of importance. The blood required for the test should be withdrawn at the same time each day, preferably before a meal, and the time and timing of each stage of the technique should be consistent throughout. It is imperative that clean and smooth test-tubes be used for the test. We have found that the "stypven" solution (thrombokinas) requires renewal every third day, and if a new solution is made up from the same batch and overlapped with the old solution errors from this source are eliminated. We have found the first appearance of granularity to be a reliable end-point of the reaction. We have investigated the usefulness of the lecithin-accelerated method of Witts and Hobson, and, although impressed at first by the sharpness of the end-point, we now believe that this advantage is offset by the shortness of the actual time measured and the possible disadvantage of introducing one more variable element.

Unexpected minor variations of prothrombin time do sometimes occur during dicoumarol administration, but we have found that by graphing the daily results and by intelligent anticipation it is possible to maintain a patient in the therapeutic range with safety. The dosage we have employed has been 300 mg. of dicoumarol on the first day, and 200 mg. on the next two days, followed by 100 mg. daily as indicated by prothrombin time. We aim to keep the prothrombin time between two and two and a half times the result determined before therapy is begun.

Secondly, we would strongly deprecate attempts to treat patients in any circumstances which do not permit of accurate daily prothrombin-time estimation. It is generally agreed that the effect of dicoumarol on the coagulation time is less consistent than the effect on the prothrombin time. Indeed, lengthening of the coagulation time is usually not seen until quite marked increase in the prothrombin time has occurred.

Thirdly, the object of dicoumarol therapy is to prevent intravascular clotting, and if therapy is to be fully effective the coagulability of the blood must not be allowed to return to normal during the treatment.—We are, etc.,

London, E.C.1.

D. J. ROBERTSON.

German Tropical Medicine

SIR,—I want to make a comment to the leading article, "German Tropical Medicine," in the *Journal* of Nov. 1, 1947 (p. 697). You write: "Bacillary dysentery caused much trouble, particularly in Poland in 1939 and in North Africa. Treatment by sulphonamides, especially sulphapyridine, was eventually introduced, although much later than in the Allied forces."

If there is the implication that Austrian and German literature, as we are using the same language, are taken together, this statement is not correct. In fact I used "prontosil" for the treatment of bacillary dysentery much earlier than the Allied forces (see Gorlitzer, V., *Schweiz. med. Wschr.*, 1940, 70, 281; Gorlitzer, V., *Klin. Med., Wien*, 1947, 2, 862).—I am, etc.,

New Delhi.

V. GORLITZER.

H.T.S.T. Pasteurization

SIR,—In your leading article of Dec. 6, 1947 (p. 914), "High-temperature Short-time Pasteurization," the efficacy of sterilization is very clearly set forth. No reference, however, is made to the effect upon vitamins. Presumably this has been estimated and been found to be no more harmful than that of the "holder process." It would be gratifying if some assurance could be given on this point.—I am, etc.,

London, W.1.

HUMPHREY NEAME.

"Unjustified" Use of d-Tubocurarine Chloride

SIR,—Many of your readers will be well aware that the advancement and perfection of obstetric anaesthesia is a cause very near to my heart, and that in these very columns I have had to defend at least one new method against the attacks of the sceptical. It was with exceptional interest, therefore, that I studied the recent replies to my letter (Nov. 22, 1947, p. 840) from Dr. H. Vincent Corbett (Dec. 13, p. 976) and Mr. Percy Malpas (Dec. 20, p. 1009). After such impressive testimony it is obvious that I overstated my ease and I unreservedly withdraw the word "unjustified" (even when garnished with inverted commas to make it less unpalatable) and hasten to effect a remorseful retreat from the ranks of the reactionaries, where I appear temporarily to have strayed. Having met my Liverpool friends more than half-way, however, I would like to add a few comments and qualify my repentance.

Of recent years, when giving general anaesthetics for caesarean section, I have been in the habit of utilizing a very light plane of cyclopropane anaesthesia with similar results to those described by Dr. T. Cecil Gray (April 5, p. 444), with the exception that our mothers did not recover consciousness "as the last stitch was tied." They did, however, make a reasonably rapid recovery—in all senses of the word—unless they happened to be in poor shape prior to operation. I cannot see that there is any virtue *per se* in awaking while in the operating theatre so long as the patient does recover uneventfully.

As is evident from this correspondence, obstetric opinion is still divided as to the necessity for abdominal relaxation during caesarean section. My remarks on the subject were of course a quotation—as will be seen from my letter—but on thinking things over I realize that I was quoting an opinion prevalent during the height of the ethereal era, when patients were very much more upset by general anaesthetics than is now the case, and also when even a small increase in anaesthetic depth might make all the difference between a lively or a lethargic infant. Under such circumstances abdominal relaxation could only be secured at the risk of a higher rate of foetal mortality and was in consequence severely discouraged.

With regard to my theory of the stimulating action of light levels of cyclopropane anaesthesia and of thiobarbiturates upon the uterus, I feel sure that Dr. Vincent Corbett cannot seriously believe that we were naive enough to base our opinion solely upon the incident—however forcefully it brought itself to our notice—of the "eyeful of liquor." In the case of thiopentone we found it next to useless for external version, owing, as far as we could judge, to tenseness of the uterus—a condition which appeared evident also during caesarean section under the same anaesthetic. If pushed to deep planes cyclopropane could be used for external version, but in the light planes employed for obstetric anaesthesia we noted the following: a tense uterus during caesarean section (the mother not being in labour) which retracted eagerly after delivery of the foetus and placenta; fairly frequent and forceful contractions during forceps delivery; and, after delivery per vias naturales, the placenta was rapidly extruded (often within a matter of minutes) and the uterus retracted to a "hard ball," rarely required the administration of pituitrin or ergometrine, and permitted of but a very small blood loss. All this naturally makes me somewhat sceptical as to the role which curare might be thought to play when thiobarbiturates, light cyclopropane, and d-tubocurarine chloride act upon the uterus in synergistic trinity.

Before the advent of curare there is little doubt that the administration of thiopentone for caesarean section reduced the whole performance to a surgical sleight of hand. Owing to the effect of the anaesthetic upon the foetus only rapid surgeons could operate successfully, and at least one obstetrician (not at King's), with a reputation for speed, is reputed to have incised skin, linea alba, peritoneum, uterine wall, and the baby's back in one heroic sweep—a "classical" operation in every sense of the word! Dr. Gray's introduction of d-tubocurarine chloride into this type of surgery, with its known property of reducing the quantity of anaesthetic otherwise necessary, appears to single out the blessings of thiobarbiturates

without their obstetric disadvantages, and I am now quite converted to the idea. If anybody is still on speaking terms with me in Liverpool I would very much like to visit them and see this anaesthetic at work.—I am, etc.,

Epsom, Surrey.

A. H. GALLEY.

Oxygen Unit for Newborn Infants

SIR,—I was interested in Dr. P. C. D. MacClanely's account (Dec. 13, 1947, p. 970) of an oxygen unit for newborn infants. We have had in use since June, 1947, at the City Lodge Hospital, Cardiff, a unit very similar to the one described, the only important difference being that the sides are made of separate pieces of 1/4 in. or 3/16 in. (0.6 or 0.45 cm.) "perspex" cemented together, and thus can be made reasonably easily by the hospital staff. We have also a larger unit which will completely cover the whole of the normal maternity cot as used at City Lodge Hospital. Both types have a detachable airtight lid allowing free access to the infant undergoing oxygen therapy without necessitating the removal of the whole unit. These units, which were designed and made by the hospital occupational therapist with the help and advice of the medical and nursing staff, have done excellent work in the hospital premature nursery.—I am, etc.,

Cardiff.

J. GREENWOOD WILSON.

Improvised Sterilizer

SIR,—The sketch illustrates an aluminium saucepan (A) with lid (B): also a "chip-basket" (C), from which the long handle has been removed, and a copper (or other rustless metal) rod (D), with a perforated-disk base. This rod pierces a hole through a metal sleeve (E) in the centre of the lid, from which the knob has been removed. The instruments to be sterilized by boiling are placed in the basket and immersed in water in the pan. The whole is boiled over a gas-ring, or, if preferred, an electric saucepan can be used. After boiling, the rod is used to lift the lid and basket from the pan. The water is poured away and the lid and basket replaced. The pan can be then gently heated to dry the instruments.

The advantages are: (1) The instruments are lifted out of the water and can be dried and cooled without contamination. Sterile forceps are ready for assembling syringes, etc., without handling the latter with fingers. (2) The whole outfit can be bought at any hardware stores and the alterations made by any tinsmith. (3) It is cheap: this cost altogether 16s. 3d.—I am, etc.,

Keighley, Yorks.

WRIGHT LAMBERT.

Natives of the Tropics

SIR,—During my stay in this country I have been attending various hospitals both in London and in Edinburgh. In all these places I have often heard the senior as well as junior doctors use the word "native" when referring to Indians, Africans, or people of any other tropical country. To give an example: "The natives suffer from beriberi more often than the Englishmen." The word "native," a reference to any dictionary will reveal, applies to the indigenous race of a country. When an Englishman therefore uses the word "natives" he should by rights refer to the natives of England. But this is not the case. The word is used by him as a contemptuous reference to the tropical races.

My coloured fellow-students who hail from China, Malaya, Burma, and India and I have often discussed this matter in the institute where I am studying. It has on quite a number of occasions caused us annoyance. We would rather be called Indian, Chinese, or Malayan than just a "native." I shall of course have no objection to being called a native of India, just

as a Frenchman should have no objection to being called a native of France, an American a native of America, or an Englishman a native of England. The word "native" used by itself when referring to the tropical races rouses in the minds of the coloured people a spirit of hatred, for it naturally reveals an arrogance on the part of the individual who uses it. I am writing this letter as a plea to the European doctors here to at least respect the feelings of the "natives" who study with them.—I am, etc.,

London, W.C.1.

M. V. CHARL.

Measles Prophylactic

SIR.—Dr. Harwood Stevenson (Dec. 6, 1947, p. 928) and Dr. A. H. Morley (Dec. 27, p. 1054) have advocated the intramuscular injection in children of parental whole blood as a routine procedure in cases of measles contacts. May I suggest that a very strong warning is needed against the indiscriminate use of such a procedure, especially in girls, because of the danger of Rh sensitization? Such sensitization, produced by the injection of Rh-positive blood rather than by pregnancy, is liable to produce a severe form of congenital haemolytic disease and, what is worse, to produce it in the first infant. The general practitioner should therefore in each individual case of contact, especially if this is a girl, balance the advantage of attenuating an attack of measles against the danger of ruining for ever this girl's chances of giving birth to normal or even live infants.

That this possibility although admittedly rare is nevertheless real and not of theoretical interest only is well demonstrated in the following case taken from Wiener's paper on the "Pathogenesis of Erythroblastosis Fetalis" (*Amer. J. Dis. Child.*, 1946, 71, 25).

Case 2.—A young woman's first pregnancy resulted in an unexplained stillbirth. She was referred to us by her physician to find out whether the Rh factor had any bearing on this problem. Results of blood tests were as follows:

Blood	Group and Subgroup	MN Type	Rh Type
Husband (wife)	0	MN	Rh +
Patient (wife)	0	M	Negative

The patient's serum did not contain any anti-Rh agglutinins, but it did contain Rh-blocking antibodies of a titre of 10. This explained the stillbirth, but it was not clear how the patient had become sensitized to the Rh factor, as she had never received a blood transfusion. On being questioned further, she recalled that ten to twelve years previously she had been exposed to measles and was given an intramuscular injection of her mother's blood, the then current method of prophylaxis. The supposition that this was the source of the sensitization was confirmed when tests of the mother showed her to be Rh-positive (group O, type Rh 2). Ironically, the patient and her mother recalled that one of us (W.) had given the injection at their paediatrician's request.

If the general practitioner has strong reasons to desire the prevention or attenuation of an attack of measles he should ask for a determination of the Rh type of the donor and the recipient. With the increasing facilities for Rh-typing, the delay involved could be made quite short, perhaps a few hours only, and in view of the grave consequences this delay and the additional labour are fully justified.—I am, etc.,

Two Mongol Children in a Family

SIR.—I was very interested in Dr. G. H. Auden's memorandum (Nov. 19, 1947, p. 869), and in view of his opinion that any such cases should be put on record because of the rarity of the occurrence, I am reporting an instance I encountered recently.

As in Dr. Auden's case, both parents were young healthy country folk, both aged 29 when the first child, a girl, was born on April 10, 1936. The second child, a boy, was born on April 23, 1942. Physically they are typical cases—brachycephalic, with short buccal cavities, short terminal phalanges, slight crooking of the little fingers, and hypotonia. There is no nystagmus, but the girl has defective vision. General development is poor, and both are imbecile. Temperamentally, they differ. The girl is rather obstinate, but on the whole happy and contented. The boy is fretful and irritable. Both are fond of music.—I am, etc.,

West Herts.

HELEN M. KEITH.

POINTS FROM LETTERS

A Sign of Appendicitis

Dr. ADALBERT DESSEWFFY (Budapest) writes: In cases of chronic appendicitis, and less frequently in subacute ones in which there are, in spite of the intraperitoneal position of the appendix, but few decided intraperitoneal symptoms, we can prove the disease of the appendix under circumstances by extraperitoneal symptoms. The technique of the examination is as follows: The patient, who is lying horizontally on his back, must be called upon to lift his upper body somewhat from the base without the help of his arms, merely by his trunk muscles, and to turn in the meantime his upper body at first entirely to the right and then entirely to the left, in order to make not only a rotating movement but also a torsion of the lumbar spinal column. In order to facilitate his making these movements we must fix his pelvis by pressure against the base. Particularly the ilio-psoas, as well as the quadratus lumborum supported by the deep back muscles, are contracted in these movements. In turning the lumbar spinal column in the opposite direction—that is, to the left—it will be the psoas, and in turning it laterally—that is, to the right—it will be the quadratus, which is more contracted. A pain in the appendix region... after turning the lumbar spinal column to the opposite side—that is, to the left—is characteristic of illness of the appendix... Sign "D" must not be overestimated; it must only be valued as part of the entire diagnosis. It must occur only unilaterally on the right side. At repeated examinations the pain will appear always at the same place—that is, in the appendix region. In gynaecological diseases "D" sign will always be negative. A pain appearing on turning the lumbar spinal column laterally to the right is mostly situated somewhat above the appendix and will rather indicate a lumbago. A rather rare pain may occur in association with sign "D" in the appendix region during active movements of the right thigh bent or much adducted or turned outwards at the hip joint when we oppose these movements.

Penile Carcinoma

Mr. DAVID M. SERR (Leeds) writes: In the discussion on the relative immunity of Jewesses to carcinoma of the uterus your correspondent states (Dec. 20, 1947, p. 1010) that this immunity is almost certainly due to the circumcision of the male. This being an unsupported statement, it would be as wise, I think, to stress what may be even more important a contributory factor—namely, the Jewish laws of separation, forbidding coitus during and for seven days after menstruation. Weinberg and Rubin, when discussing the significance of the statistical figures they had collected on this subject, suggest that the immunity is due to something in the mode and habit of life of married Jewish women. Dr. Sourasky, in a paper read at the International Cancer Conference (London, July, 1928), suggests the view that the observance of the Mosaic ritual laws by the mass of Jewish women contributed to the low incidence of cancer of the uterus. While it may be fairly logical to attribute to circumcision the immunity from cancer of the penis in Jewish males. I think it is more reasonable to stress the separation laws as being the more important contributory factor in the immunity of Jewish females from uterine carcinoma. In view of Mr. Sampson Handley's observations among the Fijians it would be interesting to know if there is in their mode of life anything comparable to this to account for their immunity from the disease.

Belladonna Poisoning

Mr. I. ISAACS (Merthyr Tydfil) writes: With reference to "Per Ardua ad Asylum's" remarks on belladonna poisoning (Dec. 27, 1947, p. 1056), he surely has given concrete examples of the dangers that exist under the present Army method of allowing dispensing to be carried out by orderlies. The obvious and vital necessity of all dispensing to be done only by qualified pharmacists is striking if we are to remove the great risk to human lives that must exist under the present system....

Plebsicite

Dr. M. DOWNEY (Leicester) writes: May I, as a general practitioner, suggest that the next plebsicite paper have only one question for answering—viz., Do you agree to enter the National Health Service in its present form? Yes or No to this one question will decide whether the profession wants to become a State-salaried service or not.

Coupons for Colostomy Belt

Dr. CHARLES J. SWANSON (Aberfeldy, Perthshire) writes: It has recently been brought to my notice that the Board of Trade demand from the sufferer from colostomy three clothing coupons before he can be supplied with the belt which makes life bearable for him. This apparently trifling exaction surely displays a callous indifference to human suffering and is one of these insulting pin-pricks which display a grossly inhuman injustice....

Obituary

D. P. FITZGERALD, B.A., M.D.

Prof. D. P. Fitzgerald, emeritus professor of anatomy at University College, Cork, died in Cork on Jan. 2, aged 76.

Denis Patrick Fitzgerald was born and educated in Cork, and in 1870 he received the degree of B.A. from the Royal University of Ireland. He began his medical studies at Queen's College, Cork, in the following year, obtaining many scholarships, exhibitions, and prizes as a medical student. He graduated M.B., B.Ch., B.A.O. in 1896. In the next year he became house-surgeon to the Cork Eye, Ear, and Throat Hospital and was made demonstrator of anatomy at Cork. This was the beginning of a long academic career. In 1907 he became lecturer in osteology, and from that time onward acted as deputy to Bertram Windle, then professor of anatomy; in the same year he was appointed lecturer in anatomy at the Cork Municipal School of Art. In 1909, on the resignation of Prof. Windle from the chair, Fitzgerald was appointed professor of anatomy at Queen's College, later known as University College. He acted as a member of the Senate of the National University, and served also on its Board of Studies. He was an examiner in anatomy at the Royal College of Surgeons in Ireland for many years. In 1940 the Senate of the University recognized his long service by conferring upon him the degree of M.D. In this year also the Faculty of Medicine at Cork made him its dean, an office which he held until his retirement from the chair in 1942, when he became professor emeritus.

"D. P.," as he was affectionately termed not only by his own students but also by many in the sister colleges, will be long remembered for his quiet and gentle manners. He was essentially a dissecting-room anatomist, one of the group which laid the topographical foundation from which the first adventures in aseptic surgery were launched. His published papers were osteological, except for an account of certain abnormal ocular muscles published in the *Journal* in 1898. His interests extended beyond the walls of his department. Like most Irishmen he had a strong sense of history, and was a recognized authority on the history of his native city and county, a topic on which he wrote much. He is survived by his widow and eight children, two of whom are members of the medical profession.—R. O. R.

JOSEPH NICHOLAS SANKEY, M.B., F.R.C.S.

Surgery in the Midlands and the Birmingham Medical School in particular have suffered a severe loss in the sudden and untimely death of Joseph Sankey, whose death on Dec. 30, 1947, at the age of 47, was due to a coronary thrombosis. His busy consulting practice, which was based on the support of a wide circle of professional friends, and his hospital appointments on the staff of the Queen Elizabeth Hospital, Birmingham, and the Guest Hospital, Dudley, occupied him so completely that he was left with little time for writing or leisure, and for months before his death he was worn down by overwork. During the period of the war especially he was taxed to the limit by his preoccupation with the Facio-Maxillary Unit at Barnesley Hall, the heavy work of which he shared with Mr. Harold Round. His special interest in plastic and facio-maxillary surgery slowly emerged some years ago out of a broad basic training in general surgery, and latterly he was seeking to shed some of his general surgical work and concentrate more and more on his specialty. However, he never took a clear-cut step to achieve this. Loyalty to old practitioner friends, and a sincere attachment to the wider aspects of surgery, delayed his decision, and his professional life was over full largely because of this double burden.

Joseph Nicholas Sankey was a student at Birmingham and at the Middlesex and London Hospitals. He graduated M.B., Ch.B. in 1923, and took the F.R.C.S. in 1926. He held resident appointments at the General Hospital, Birmingham, and in London at the Samaritan Hospital and Queen Charlotte's, where he was R.M.O. After his appointment in 1932 as assistant surgeon to the Queen's Hospital, Birmingham, he went to America for a period of study leave which he spent mainly

at the Mayo Clinic, where the inspiration and example of William and Charles Mayo exercised a permanent influence on his surgical education and gave him a scientific outlook on surgery so valuable to one about to take up his duties in a medical school. Later, under the influence of Kilner, he became interested in plastic surgery, and with the impact of war he transferred his interest more and more to this aspect of his work. In his specialty he was deft and ingenious and had that touch of artistry which is essential to success in this branch of surgery; furthermore, his friendly and sympathetic approach secured the confidence and co-operation of his patients in their tedious and prolonged reconstruction operations.

Sankey had a great capacity for friendship. To run across him was always a pleasure, and though his days were full he gave the idea that he had not a care in the world and found nothing but pleasure in your company and happiness in the chance encounter. He faced life with great courage. He never intruded his troubles upon his friends and he appeared to be wholly at the disposal of any patient or friend with whom he came in contact. Many of his qualities arose out of his somewhat unusual background. Born in a Herefordshire village home, his family migrated to Canada in his childhood, and his boyhood was spent on a Canadian farm, whence, just before the 1914 war, his parents brought him on holiday to this country. Caught by the war, they had great difficulty in returning home, but eventually managed to do so, leaving the boy behind at the age of 16 at the Newport Grammar School. From this time onwards he maintained himself through his school and university days until he qualified. His experiences during this period gave him his broad outlook on life and made him very tolerant and happy in association with all classes in the community. His varied experiences during this uphill period, as a violinist in a band, as a factory worker, or as a farmhand, remained all his life as a not unhappy memory, about which he could occasionally be persuaded to speak with a whimsical humour which was a part of his charm.

The very large attendance at the Memorial Service in St. George's Church, Edgbaston, afforded a striking testimony to the widespread respect in which he was held in the community in which he worked. Sankey was unmarried, and most of his relatives are in Canada, and it was fortunate that last autumn he found it possible to visit his father in the course of a flying visit to Vancouver which gave him great pleasure and some relief from the strain of practice.—S. G. B.

Dr. H. S. Littlepage writes: "Joe" Sankey's academic career and ability as a surgeon were brilliant. His kindness to the sick and his loyalty to general practitioners were among many outstanding qualities which he possessed, and many of us will always remember him as the "G.P.'s" friend. A call for his help at any hour of the day or night, to the rich or to the poor was always answered in the same cheery way: "Sure, I'll be along." He had an amazing insight into a patient's character and any fear of the operation or the anaesthetic seemed to fade away at his reassuring smile and sincere understanding. Young residents will also miss him greatly. So will his nurses. And anaesthetists will always remember his kindness, his patience, and his understanding when they were in difficulty.

C. A. MITCHELL, M.A., D.Sc.

Dr. C. A. Mitchell, at one time editor of the *Analyst* and a former president of the Medico-Legal Society, died on Jan. 5 at the age of 80.

Charles Ainsworth Mitchell, the third son of Dr. T. R. Mitchell, was born at Thetford, Norfolk, and was educated at King William's College in the Isle of Man, and at Exeter College, Oxford. He became a Fellow of the Royal Institute of Chemistry in 1897, two years after graduating, and his early interest in chemistry led him to an unusual but useful study—that of the history and analysis of inks. His book on the subject, which is already in its fourth edition, has become a standard reference work and is consulted when questions of the authenticity of legal documents of whatever age arise. For many years he contributed articles on scientific subjects, often of legal interest, to *Chambers's Journal* and to *Discovery* and other periodicals. He was president of the Medico-Legal Society from 1935 to 1937, honorary vice-president of the Medico-Legal Society of France, and vice-president of the Royal Institute of

B.D.H. SEX HORMONES

for implantation

Sex hormone administration by implantation has many advantages over oral or parenteral treatment in those cases in which continuous action of the hormone is desired.

The need for frequent injections is eliminated and the natural continuous secretion of hormone is more closely simulated than is possible from injection even of esterified hormones in oily solution.

B.D.H. Sex Hormone Products are available in pellets for implantation as follows :—

	Price per pellet
OESTROFORM (aestradiol) 20 mg.	30s. 0d.
PROGESTIN B.D.H. (progesterone) 100 mg.	50s. 0d.
TESTOSTERONE PROPIONATE B.D.H. 100 mg.	42s. 6d.

SHor/E/178a

Hepolon is produced by special processes which conserve all the known hæmatopoietic principles of the whole liver. It approximates to the extract described by Gämslen.

Hepolon not only passes the highest clinical tests for potency against pernicious anæmia but contains Whipple's factor, Wills's factor, riboflavine, nicotinic acid, and the hæmatinic minerals of liver; it gives no reactions for histamine or undesirable protein matter.

Ampoules of 2 c.c.; box of 6, 6/-, box of 12, 11 6/-, and box of 24, 22/-
Rubber-capped vial of 10 c.c., 5/-, and of 30 c.c., 12 6/-

HEPOLON

Contains in 100 c.c. the total solid extractive matter of 2.0 g. fresh liver.

**Put out
that cold!**

The use of 'Benzedrine' Inhaler at the first sign of a cold will often cut short the condition entirely. In the acute stages marked symptomatic relief can be obtained and the onset of serious complications prevented. The vapour diffuses throughout the nasal cavity, reaching and relieving congestion wherever it exists.

'BENZEDRINE' INHALER

Indicated in HEAD COLDS, SINUSITIS, NASAL CATARRH and HAY FEVER

Each tube is packed with Amphetamine (B.P.) 325 mgm., Oil of Lavender 97 mgm., Menthol 32 mgm.

"Colds are like fires; the easiest and most certain time to put them out is at the earliest onset, but prompt action is essential."

British Medical Journal,
June 30th, 1945, p. 926.

10,000 MEDICAL MEN

Aren't Likely To Be Wrong

It is our good fortune to be of service to thousands of medical men—both in hospitals and in private practice.

The items we find most useful to them are our standardised Case History (visible) records, our Accounts (visible) records and our desk-top units.

The visible records afford the doctor a simple method of controlling his case-histories and accounts, visually, of signalling interviews and special cases and of annotating diagnoses,

prescriptions, family histories, etc. Portable books holding these records make patients on the "visiting" list a simple problem.

The desk unit is a species of silent "secretary" in that it brings forward reminders of appointments and other matters, houses all relevant papers, etc., and, if necessary, provides a covered-in file with a slotted-in record in front for annotating. These latter folders are also widely used for X-ray negatives and the like.

Full details (and free specimen records) will be sent to you if you will just write "Records" on your note-paper or visiting card.

SOLVE THOSE SEARCHING PROBLEMS

'Haliverol'

*The result of long and varied experience
in Vitamin research and Vitamin assay*

'Haliverol' is a rich source of the fat-soluble vitamins A and D. It is standardized to contain in each grammic 27,000 International units of Vitamin A and 5,400 International units of Vitamin D, and each capsule contains 4,500 International units of Vitamin A and 900 International units of Vitamin D.

'Haliverol' provides a markedly active preparation and assures adequate intake of these vitamins without imposing unpalatable medication or altering the dietetic balance.

It is standardized, and complete reliance may be placed on its vitamin activity.

The Parke, Davis & Co. Laboratories have the benefit of 28 years' experience in vitamin study, and of extensive manufacturing operations, especially in the production of halibut-liver oil. These laboratories not only did pioneer work in vitamin preparations, but also, in co-operation with another laboratory, developed the first commercial production of vitamin preparations from halibut livers.

'Haliverol' is available in vials of 5 c.c. and 50 c.c. each with a dropper. It is also supplied in packages of 25 and 100 capsules.

Chemistry from 1937 to 1940. Among his other publications were *Science and the Criminal* in 1911; *The Evidence of the Casket Letters* in 1929; and *The Scientific Detective and the Expert Witness*, which appeared in 1931.

Dr. HENRY MARTIN MOGRIDGE WOODWARD, who died on Jan. 2 at his residence at Blackheath, was the son of the late Dr. Martin Woodward, of Pershore, Worcestershire. He was educated at St. Edward's School and Keble College, Oxford, and later at Guy's Hospital. In his younger days and until illness overtook him he was a keen athlete and rowed for his college. For a time he was on the stage, playing chiefly Shakespearean roles, but later he took up medicine and qualified in 1904. Soon after qualification he became house-surgeon to St. John's Hospital, Lewisham, and he devoted the rest of his life to the interests of that hospital. He was bacteriologist to the hospital for over thirty years, and although he had reached the age for retirement when the recent war broke out he continued his devoted services, attending the hospital daily, including Sundays, without any holiday. This undoubtedly had a serious effect on his health. He was not robust and had had several severe illnesses. At St. John's Hospital Dr. Woodward met and married Miss Elizabeth Thompson, and their partnership was an ideally happy one. He was consulting bacteriologist to several hospitals in South-east London and Kent, but his chief interest always remained St. John's Hospital, to the exclusion of private practice. At the time of his death he had been a governor of the hospital for more than twenty-five years and gave of his utmost in the interests not only of the patients but also his medical colleagues. On his retirement from active service with St. John's in 1946 he was elected to the consulting staff and also continued as a governor, maintaining his close interest in the hospital's affairs. He attended a board meeting a few weeks before his sudden death. Dr. Woodward was a very scholarly man and retained his interest in the classics until the end. He was a keen supporter of the Medico-Legal Society and was interested in and worked for several charities. He was indeed one of the most charitable of men and never spared himself whenever he saw an opportunity to be of help. Our deepest sympathy goes out to Mrs. Woodward, who nursed him so devotedly through several serious illnesses.—P. F. A.

Dr. ARTHUR CHARLES INGRAM died on Dec. 20, 1947, at Bournemouth. He was educated at Felsted School, Cambridge University, and Charing Cross Hospital. He qualified in 1900 and graduated in 1901, subsequently proceeding M.D. and taking the M.R.C.P. He held the Cambridge D.P.H., and he entered the Indian Medical Service in 1904, taking the gold medal for military medicine at Netley. He was at one time professor of pathology in the University of Madras. He left the Service in 1921 with the rank of major and was appointed bacteriologist to the Borough of Bournemouth in 1922, holding this appointment up to the time of his death. His sudden death came as a shock to his friends and colleagues in Bournemouth.

Dr. ELIZABETH COURTAULD, who died on Dec. 26, 1947, had been living in retirement very much crippled for some years. She started medical work at the Royal Free Hospital rather later than usual, as she had taken nursing training earlier. She was in residence at College Hall through all her medical course. After qualifying L.S.A. in 1901 she took the M.D. of Brussels in 1903, and went into general practice for a short time. She then did medical mission work in India, principally at the Church of England Zenana Mission Hospital at Bangalore. In the 1914-18 war she was attached for some time to the Scottish Women's Hospital at Abbeville de Royaumont, in France. Although frail physically, she was always at work and took practically no time off—she did not object to the other medical officers taking time off but was merely mildly surprised that they should want to do so. Her bent was medical, but she collaborated with Miss Ivens in any surgical or anaesthetic or other work that wanted doing. She had been in retirement near Halstead for some years enjoying the quiet and the opportunity to keep in touch with her family in that neighbourhood.—L. M. P.

Dr. JOHN HEWETSON WHITESIDE died at Hadlow, Tonbridge, on Dec. 31 at the age of 84. The third son of the Rev. Stephen Whiteside, he was educated at Appleby Grammar School and Edinburgh University, and graduated M.B., C.M. in 1886. He was in general practice in recent years at Armitage, near Rugeley, Staffordshire, and he was medical officer of the Rugeley Cottage Hospital, medical officer and public vaccinator for the Rugeley District, police surgeon, and divisional

surgeon to the Rugeley Ambulance Brigade. He had served as a captain in the R.A.M.C. in the 1914-18 war. He was always actively interested in the work of the St. John Ambulance Brigade and he was an expert amateur carpenter. Among other things he made an altar, which is still in use at Armitage Church.

Dr. FRANK HARRIS WHITE died in London on Jan. 2 at the age of 75. A student of the London Hospital, he took the L.S.A. in 1893, the conjoint diploma two years later, and the D.P.H. in 1900. He was at one time aural assistant to the London Hospital, and he was in general practice in the East End of London, first in Bow and later in Poplar, until 1930. He served in the R.A.M.C. in the 1914-18 war and was regimental medical officer to the 17th London Regiment, leaving the service with the rank of major. He was appointed medical officer to the Port of London Authority in 1930, which post he held until the time of his death. He leaves a widow, two sons, and two daughters.

Dr. ANNA POLLOCK MARTIN died in Southampton Hospital on Jan. 5. A daughter of the late Rev. William Martin, who was a missionary in Rajputana, she was born there and educated at the Park School, Glasgow, and at Glasgow University, where she graduated in 1903, proceeding M.D. in 1906. She was in private practice in Ayr for some time before being appointed in 1920 as a Church of Scotland missionary to the Mure Memorial Hospital, Nagpur. This is a large, well-equipped women's hospital which serves a large section of the Central Provinces. In the course of her work there Dr. Martin took a prominent part in the medical and welfare work of the community. In 1942 she was awarded the Kaisar-Hind medal for her services in this connexion.

Universities and Colleges

UNIVERSITY OF LONDON

Dr. E. Ashworth Underwood, Director of the Wellcome Historical Medical Museum, will deliver a course of six public lectures on "The Heritage of Medicine" in the Department of Physiology, University College, Gower Street, W.C., on Fridays, at 5 p.m., from Jan. 23 to Feb. 27.

A course of four public lectures on "Some Aspects of General Physiology" will be given by L. E. Bayliss, Ph.D., Reader in Physiology in the University, in the Department of Physiology, University College, on Tuesdays, March 2, 9, 16, and 23, at 5 p.m.

A course of five public lectures on "Some Aspects of Pharmacological Chemistry" will be delivered by F. Bergel, Ph.D., in the Physiology Theatre, Gower Street, W.C., on Tuesdays, at 5.15 p.m., from Jan. 20 to Feb. 17.

Admission to the lectures is free, without ticket. Students and others interested are invited to attend.

Prof. Osten Holsti, professor of general medicine in the University of Helsinki, has come to work at the Postgraduate Medical School of London in the Department of Medicine for three months as a visiting professor. Prof. Holsti has just been honoured on his sixtieth birthday by the issue of a congratulatory number of the *Annales Medicinæ Internæ Fennicæ*, written and dedicated by his pupils. He is one of the leaders of clinical medicine in Finland and has done distinguished work on arthritis, diabetes, and haematology. While he is in London he will take part in teaching and research in the Department of Medicine at the Postgraduate Medical School.

The following candidates have been approved at the examinations indicated:

M.D.—BRANCH I (Medicine): D. W. R. Ashby, W. J. Atkinson, T. P. Blanshard, F. E. de W. Cayley, A. H. C. Couch, H. D. Crosswell, E. M. C. Dunlop, C. G. Fagg, J. H. Friend, T. Hanley, S. W. Hinds, E. A. Hunter, S. L. Kaye (Gold Medal), P. M. McAllan, Catherine A. Neill, T. Partington, C. E. Quinn, H. W. Salmon, G. Shennerson, Esther E. Simpson, Jean V. Simpson, W. F. T. Tatlow, J. W. Thompson, P. A. Thorn, A. S. Watts, D. Weitzman, P. E. D. S. Wilkinson, Judith C. M. Yuill. BRANCH II (Pathology): D. B. Brewer, G. Discombe, B. P. Marmion, H. C. Moore, K. B. Rogers. BRANCH IV (Midwifery and Diseases of Women): S. F. Hans. BRANCH V (Hygiene): J. J. A. Blakely, W. C. D. Lovett, C. D. L. Lycett, C. Seelye. BRANCH VI (Tropical Medicine): K. P. Hare (Gold Medal), V. G. Patel, A. J. Walker.

UNIVERSITY OF BRISTOL

George Lionel Alexander, F.R.C.S., has been appointed Director of the Neuro-Surgical Unit in the University.

The following candidates have been approved at the examinations indicated:

M.D.—D. N. Walder.
FINAL M.B., Ch.B.—Margaret J. Andrews, D. H. Bowden, D. McL. Cunningham, Eudora M. R. Davies, N. M. Gibbs, Pamela H. L. Hamilton, S. P. Iles, Jean E. Mortell, Josephine C. Mulcahy, J. P. Norris, P. W. Seacrest. In Group I, completing the examination: Catherine M. Hyle. In Group II completing the examination: C. E. Halliday, Kathleen C. Iles.
DIPLOMA IN PSYCHOLOGICAL MEDICINE.—Part II: L. B. Thomas

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Dec. 27.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1947					1946 (Corresponding Week)				
	(a)	(b)	(c)	(d)	(e)	(a)	(b)	(c)	(d)	(e)
Cerebrospinal fever ..	26	4	16	1	—	38	3	23	2	1
Deaths	—	1	1	—	—	—	1	—	—	—

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore in approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

EPIDEMIOLOGICAL NOTES

Paratyphoid at Ipswich

Since Dec. 20, 1947, there have been 22 cases of paratyphoid B notified in Ipswich, with one death, and 8 carriers have been isolated among the contacts. In the county of Suffolk within a radius of a few miles 26 cases have appeared, and there have been 3 cases in Essex.

Dec. 4 and 6 were outstanding dates of presumptive infection in the Ipswich cases up to Jan. 6. The three cases in Essex are not yet linked up with the Ipswich outbreak. Organisms cultured from 35 infections in this outbreak are reported to belong to phage type I.

Investigation of the cases suggested confectionery as the vehicle of infection, the most common reference being to cream-filled buns or cakes. Within a few days an infected person was found who had been handling such foodstuffs for the first three weeks of December. It has not, however, been possible to isolate the organism from samples of such food taken after Dec. 20.

Poliomyelitis in Scotland

The number of suspected and confirmed cases intimated by medical officers of health to the Department of Health for Scotland between June 1, 1947, and the end of the year was approximately 1,675—the highest number ever recorded in Scotland. In June and July together, about 100 cases were notified. Approximately 520 cases were reported in August, and 590 in September. Thereafter the numbers fell to 325 in October, 100 in November, and 48 in December. Suspected cases were reported in every county except Orkney and Ross and Cromarty and in every large burgh except Inverness.

The greatest number of cases reported in any one area was 483 in Glasgow; 138 cases were reported in Edinburgh, 51 in Aberdeen, and 39 in Dundee. In the county areas the greatest number of reported cases was in Ayrshire, with 108 cases. Lanarkshire had 105 cases, and Morayshire and Fife 56 each. No other county or large burgh had more than 50 cases.

The deaths from poliomyelitis usually amount to about 5 to 10% of the cases, and in the 1947 epidemic the total number of deaths recorded in the 16 principal towns in Scotland between June 1 and the end of the year was 69 out of 865 cases.

Poliomyelitis in England and Wales

Notifications of poliomyelitis 59 (44) for the week ended Jan. 3 showed a slight rise on those of the previous week, and those of polio-encephalitis are the same 4 (4). Figures for the previous week are shown in parentheses. It is possible that the Christmas holiday may have led to some delay in notification and that the slight rise may be more apparent than real.

Discussion of Table

In England and Wales a large decrease was recorded in the notifications of all infectious diseases except paratyphoid fever, which increased by 16. There were falls in the incidence of measles 626, whooping-cough 558, scarlet fever 594, acute pneumonia 151, and dysentery 30.

The largest falls in the notifications of measles were Lancashire 111, Nottinghamshire 81, Derbyshire 75, Northamptonshire 47. For scarlet fever the most marked declines in incidence were Staffordshire 70 and London 55 and for whooping-cough Lancashire 71 and Middlesex 61.

The fall in the incidence of acute pneumonia was confined to the southern and midland counties. The chief features of the returns for diphtheria were decreases in Lancashire 18 and Essex 15.

Of the 22 notifications of paratyphoid fever 17 were recorded in five administrative areas of Suffolk. In Surrey, Epsom and Ewell M.B., 8 further cases of dysentery were notified, and the only other large return was Lancashire 21. The largest returns of poliomyelitis were Cheshire 4 and Lancashire 4.

In Scotland a decreased incidence was recorded for every infectious disease except diphtheria, which increased by 8. There were falls in the incidence of measles 223, acute primary pneumonia 32, whooping-cough 18, and acute poliomyelitis 10. The increase in the incidence of diphtheria was mainly in the western area, where the notifications rose from 40 to 51. Only 3 cases of poliomyelitis were notified, 2 in Glasgow and 1 in the county of East Lothian.

In Eire a decreased incidence of infectious diseases was also recorded. The notifications declined for measles 46, scarlet fever 26, and diarrhoea and enteritis 17.

In Northern Ireland the chief features of the returns were falls in the notifications of scarlet fever 35, measles 12, and diphtheria 8.

Week Ending January 3

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,786, whooping-cough 1,891, diphtheria 225, measles 4,490, acute pneumonia 1,098, cerebrospinal fever 55, acute poliomyelitis 59, dysentery 86, paratyphoid 39, and typhoid 5.

Medical News

More Beds for Streptomycin Treatment

The total number of beds available at hospitals in the United Kingdom for the treatment of patients with streptomycin has been increased from 150 to about 200, and the following additional hospitals are now able to provide treatment:

- University College Hospital, London.
- Addenbrooke's Hospital, Cambridge.
- Radcliffe Infirmary, Oxford.
- King's Cross Hospital, Dundee.

All the hospitals concerned have been asked to continue restricting treatment with the drug to cases of tuberculous meningitis and miliary tuberculosis. Medical practitioners who have such cases should get into touch with the nearest convenient hospital with beds reserved for streptomycin treatment, or, in the case of hospitals in the London area, with the Emergency Bed Service (telephone, Monarch 3000). Other hospitals at which this treatment is available were listed in our issues of Sept. 6, 1947 (p. 399), and Oct. 4, 1947 (p. 555). The Ministry of Health emphasizes that despite these additional beds it is unlikely that all cases of these two types of disease can be accommodated at present.

Dr. Voeller and Parkinson's Disease

The Information Services Directorate of the Foreign Office (German Section) issued the following statement on Jan. 7: "Some publicity has recently been given to reported cures of Parkinson's disease (paralysis agitans) effected by a Dr. Voeller, of Kassel (U.S. Zone of Germany). The story originated from a recommendation alleged to have been made by the notorious Dr. Karl Brandt to a British soldier. Dr. Voeller once owned a private nursing-home in Kassel where he specialized in the treatment of this disease, and where, with close attention to the well-being of his patients, he appeared to obtain some good results. According to Public Health Branch of the Control Commission for Germany (B.E.), there is no truth in the report that Dr. Voeller has discovered a specific cure for Parkinson's disease. It is emphasized that periods of apparent improvement are a characteristic of the development of the disease. Dr. Karl Brandt, Reich Commissioner for Health under Hitler, was sentenced to death by hanging on Aug. 20, 1947, by a United States Military Court at Nuremberg after being found guilty of crimes against humanity and sadistic experiments on human beings in German concentration camps."

M.R.C. Dental Research Committee

The Medical Research Council have recently reconstituted the Dental Research Committee. The secretary of this committee is Prof. M. A. Rushton, Department of Dental Medicine, Guy's Hospital.

Irish Postgraduate School

The Eire Minister for Health has appointed a committee to examine the facilities at St. Kevin's Hospital, Dublin, and to make recommendations about measures needed to establish there a post-graduate medical school for medical-officers employed by local authorities.

Psychiatric Committee

The Representative Psychiatric Committee of the North-east Metropolitan Area consists of elected representatives of the medical staffs of the mental hospitals, the mental deficiency institutions, and the psychiatric departments of the teaching and non-teaching general hospitals in the area. It has been in existence since June, 1947, and has as its terms of reference: "To consider and to concern itself with every aspect of the psychiatric services in the region." The committee is under the chairmanship of Dr. Henry Wilson.

Illustrating Pathology

A number of students have been trained at the St. Martin's School of Art in the technique of drawing pathological and surgical specimens. Part of their experience has been gained in operating theatres in London hospitals. Their services are now available for employment by surgeons or hospitals. Inquirers should write to the principal of the school, 109, Charing Cross Road, W.C.2.

Scabies Order

Under the Emergency Laws (Transitional Provisions) Act, 1946, and the Emergency Laws (Miscellaneous Provisions) Act, 1947, Regulation 33A of the Defence (General) Regulations, 1939, expired on Dec. 31, 1947, and the Scabies Order, 1941, which was made under that Regulation, accordingly ceased to be operative after that date. The Regulation and the Scabies Order were introduced as an emergency wartime measure to combat an exceptional increase of scabies. The time has now come, in the view of the Minister of Health, to revert to reliance on normal statutory powers, as contained in the Public Health Acts, for dealing with verminous conditions.

Demand for Blood Increases

During the June quarter 27,546 new donors joined the National Blood Transfusion Service, reports the Ministry of Health. This is about twice as many as in the first quarter. Blood was given by 66,557 donors. The estimated donor panel strength is now about 350,000. To provide for further increases in the demands for blood and plasma, and to ensure that donors are not asked to give blood more often than once every six months, some 168,000 new volunteers are required in England and Wales.

Prof. G. Grey Turner

George Grey Turner, M.S., F.R.C.S., Emeritus Professor of Surgery in the University of London, has been elected an Honorary Member of the Greek Surgical Society and a Corresponding Member of the Royal Academy of Medicine of Belgium.

Freedom of Kirkcudbright

John MacMyn, M.D.Ed., has been given the freedom of the Royal Burgh of Kirkcudbright.

Appointments for War Service

William Archibald Balheicht, L.M.S., Medical Officer, Malayan Medical Service, has been appointed O.B.E. (Civil Division), and Yeoh Bok Choon, L.M.S., Tutor in Surgery, College of Medicine, Singapore, has been appointed M.B.E. (Civil Division), for services at the Tan Tock Seng Hospital, Singapore, during the enemy occupation.

Wills

Mr. Louis Carnac Rivett, the well-known obstetrician and gynaecologist, who died on Sept. 5, 1947, left £17,793. Dr. Isabella Macdonald Macdonald, formerly consulting physician to the Elizabeth Garrett Anderson Hospital, left £17,590. Dr. Herbert William Allan, late M.O.H. for Wells, left £1,333. Dr. Sidney Herbert Daukes, formerly curator of the Wellcome Museum, who wrote novels under the pseudonym of Sidney Fairway, left £6,490.

COMING EVENTS

Ophthalmological Society of the United Kingdom

The annual congress of the Ophthalmological Society of the United Kingdom will be held at the Royal Society of Medicine, 1, Wimpole Street, London, W., on Thursday, Friday, and Saturday, April 8, 9, and 10, when the subject for discussion will be "Subjective Disorders of Vision (excluding those due to local ocular disease)," to be opened by Dr. Macdonald Critchley, Prof. Henry Cohen, and Mr. J. H. Doggart. The Bowman Lecture will be delivered by Prof. Marc Amsler (Zurich). Members who wish to read papers are asked to send the titles to Mr. T. Keith Lyle, F.R.C.S. (honorary secretary for congress business), 42, Charles Street, Berkeley Square, London, W.1, as soon as possible. Abstracts of papers, which will be circulated at the congress and subsequently to the leading ophthalmological journals abroad, should be submitted by Jan. 31. On Friday afternoon (April 9) there will be a joint clinical meeting with the Ophthalmological Section of the Royal Society of Medicine at the Ophthalmic Institute, Central London Ophthalmic Hospital, Judd Street, London, W.C. Those who wish to show cases are asked to communicate with the registrar-tutor, Mr. H. Ryan, at the hospital. The annual dinner will be held at the Royal College of Surgeons of England (Lincoln's Inn Fields, London, W.C.) on Thursday, April 8. Owing to official restrictions the numbers on this occasion will be limited to 100, and it is regretted that it will not be possible to allow members to bring guests.

Association of Clinical Pathologists

The 39th scientific meeting of the Association of Clinical Pathologists will be held at St. Mary's Hospital, London, W., on Friday and Saturday, Jan. 30 and 31. The programme is as follows: Jan. 30, 9.30 a.m., Prof. R. J. V. Pulvertaft, Stabilization of penicillin solutions by phosphates; 9.45 a.m., Dr. J. Ungar, Comparison of penicillin blood levels after aqueous solutions and oily suspensions of penicillin; 10.5 a.m., Dr. M. Daniels, The value of streptomycin; 10.35 a.m., Dr. Tullio de Sanctis Monaldi, Modification du liquide céphalo-rachidien dans la méningite tuberculeuse, traitée par la streptomycine; 11.25 a.m., Dr. G. B. Forbes, Relative merits of laryngeal

swabs and fasting stomach contents in the detection of tubercle bacilli; 11.50 a.m., Dr. A. F. S. Sladden, A convenient technique for the Aschheim-Zondek Test; 12.15 p.m., Mr. R. E. Glover, Supply of laboratory animals; 12.35 p.m., Dr. Georgiana M. Bonser, Pigmented tumours of the skin; 4.30 p.m., Presidential address by Dr. C. E. Duke, Human relationships in clinical pathology; 5.10 p.m., presentation to Dr. S. C. Dyke (Founder of the Association); 5.15 p.m., Reply by Dr. Dyke with an address entitled "Genesis." Jan. 31, 9.30 a.m., Dr. K. S. Thompson, Evolution of an antiseptic lubricant; 9.55 a.m., Dr. R. M. Haines, Observation on the histology of tuberculous endometritis; 10.15 a.m., Mr. J. T. Duncan, Histoplasmosis; 10.40 a.m., Dr. J. R. O'Brien, Significance of the bleeding time; 11.30 a.m., Dr. J. V. Joossens, Reticulocyte counts by fluorescence microscopy; 11.50 a.m., Dr. G. Discombe and Mr. H. Meyer, Capillary method of rhesus grouping; 12.10 p.m., Dr. J. Harkness, Significance in clinical pathology of the variations in the hypothetical equilibrium of the plasma proteins; Dr. W. W. Payne, Biochemical aspects of gastro-enteritis; 2.30 p.m., Dr. J. C. Colbeck, Air embolism and the method of post-mortem diagnosis; 2.55 p.m., Dr. C. J. Lind, Blood alcohol, its determination and interpretation; 3.15 p.m., Dr. F. E. Camps, Medico-legal problems of the newborn child; 3.40 p.m., Mr. H. S. Holden, Laboratory aspects of drowning. Demonstrations will be given from 2 p.m. on Jan. 30 to 12 noon on Jan. 31. The honorary secretary of the association is: Dr. W. H. McMenemey, Royal Infirmary, Worcester.

Services Hygiene Officers' Dinner

A reunion dinner of the Navy, Army, and Air Force Hygiene Group of the Society of Medical Officers of Health will be held at Stewart's Quadrant Restaurant, 74, Regent Street, London, W., on Friday, Jan. 30, at 6.45 for 7.15 p.m. Any serving or former hygiene officers in any of the Services will be welcome. Early applications for tickets should be made to the honorary secretary, Dr. H. D. Chalke, O.B.E., Public Health Department, 33-5, Lancaster Grove, London, N.W.3, enclosing remittance for 16s. 6d. (which includes coffee and tips but not wines or spirits). The chair at the dinner will be taken by the Group's president, Brigadier A. E. Richmond, C.B.E., Director of Hygiene, A.M.S., who at 5.30 p.m. the same day will deliver his presidential address on "The Army's Health in 1947" at B.M.A. House, Tavistock Square, London, W.C.

American Group Therapy Association

The annual meeting of the American Group Therapy Association will be held at Hotel Commodore, New York City, on Sunday, April 11, 1948. The programme will include case presentation and discussion and an evening session devoted to reports and evaluation of current practices and trends in group therapy. A copy of the preliminary programme and further information may be obtained from the association at 228, East 19th Street, New York 3, N.Y., U.S.A.

SOCIETIES AND LECTURES

Monday

HUNTERIAN SOCIETY.—At the Mansion House, London, E.C., Jan. 19, 8.30 p.m. "Recent Improvements in the Diagnosis and Treatment of Vascular Obstruction." Hunterian Lecture by Prof. J. Cid Dos Santos (Lisbon).

Tuesday

EUGENICS SOCIETY.—At Royal Society's rooms, Burlington House, Piccadilly, London, W., Jan. 20, 5.30 p.m. "Sex Limitation in Human Genetics." Dr. H. Harris.

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C., Jan. 20, 5 p.m. *Pathological Demonstrations.* Dr. I. Muende

SOCIETY FOR THE STUDY OF ADDICTION.—At Medical Society of London, 11, Chandos Street, W., Jan. 20, 4 p.m. "Economic Aspects of Tobacco Addiction." Mr. V. Zachary Cope. Followed by discussion.

UNIVERSITY COLLEGE LONDON: DEPARTMENT OF PHARMACOLOGY.—Jan. 20, 5.15 p.m. "Introduction: Pharmacology and the Chemical Sciences." Mr. F. Bergel.

Wednesday

ROYAL MICROSCOPICAL SOCIETY.—At B.M.A. House, Tavistock Square, London, W.C., Jan. 21, 5 p.m. for 5.30 p.m. "Relation between Cellular Structure and Functional Activity." Presidential Address by R. J. Ludford, Ph.D., D.Sc.

ROYAL SANITARY INSTITUTE.—At Town Hall, Colchester, Jan. 21, 2 p.m. "The Implementation of the National Health Service Act in County Districts." Dr. J. D. Kershaw.

Thursday

MEDICO-LEGAL SOCIETY.—At 26, Portland Place, London, Jan. 22, 8.15 p.m. "The Office and Duties of the Director of Public Prosecutions." Sir Theobald Mathew, Director of Public Prosecutions.

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, Hyde Park Corner, London, S.W.—Jan. 22, 4.30 p.m. *Neurological lecture-demonstration.* Dr. A. Feiling.

Friday

ROYAL COLLEGE OF OBSTETRICIANS AND GYNAECOLOGISTS, 58, Queen Anne Street, W.—Jan. 23, 5 p.m. "Primary Carcinoma of the Vagina." William Blair-Bell Memorial Lecture by Dr. Stanley A. Way.

LONDON CHEST HOSPITAL, Victoria Park, E.—Jan. 23, 5 p.m. "Radiological Diagnosis in Trauma of the Lungs." Dr. C. J. Hodson.

MIDDLESEX COUNTY MEDICAL SOCIETY.—At Hillingdon County Hospital, near Uxbridge, Jan. 23, 3 p.m. Agenda: Demonstration of clinical cases and pathological material, including cases of congenital disease of lungs, heart, and aortic arches. The Department of Physical Medicine is open and there will be demonstrations of cases and treatment. "Physical Methods in Rehabilitation." Short paper by Dr. Talbot; "Value of Radiology in Diagnosis of Acute Abdomen." Short paper by Dr. Maddocks.

ROYAL MEDICAL SOCIETY, 7, Melbourne Place, Edinburgh.—Jan. 23, 8 p.m. "Body and Mind." Address by Mr. K. M. Walker.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—At South Kensington Hotel, 41, Queen's Gate, S.W., Jan. 23, 8.30 p.m. "Modern Surgical Treatment of Chronic Peptic Ulcer." Opening speakers, Dr. A. Morton Gill and Mr. I. M. Orr. Discussion.

UNIVERSITY COLLEGE LONDON: DEPARTMENT OF PHYSIOLOGY.—Jan. 23, 5 p.m. "The Fabric of the Human Body." Dr. E. A. Underwood.

Saturday

BIOCHEMICAL SOCIETY.—At British Postgraduate Medical School, Ducane Road, Hammersmith, London, W., Jan. 24, 11 a.m. 263rd meeting.

BRITISH ASSOCIATION OF ALLERGISTS.—At Wright-Fleming Institute of Microbiology, St. Mary's Hospital, Paddington, London, W., Jan. 24, 2.30 p.m. First general meeting. "Forty Years of Allergy." Dr. John Freeman; "Advancing to the Future in Allergy—A Brief Survey." Mr. Frank Coke.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES.—At 11, Chandos Street, London, W., Jan. 24, 2.30 p.m. "Treatment of Neurosyphilis with Penicillin." Dr. J. Purdon Martin. Discussion.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Ancombe.—On Dec. 28, 1947, at Crumpsall Hospital, Manchester, to Maureen (née Macandrew, M.B., Ch.B.), wife of Dr. A. R. Ancombe, a son.

Aspin.—On Jan. 5, 1948, at The Willows Nursing Home, Bramley, Leeds, to Alice and Dr. John Aspin, a daughter.

Gifford.—On Jan. 3, 1948, at Mill Road Hospital, Liverpool, to Gwen (née Hayes), wife of Dr. J. Hamilton Gifford, a daughter—Valerie.

Hay.—On Dec. 15, 1947, at Sunderland, to Vera (née Brown), and Dr. Arthur W. Hay, a daughter—Vivienne Margaret.

Maughan.—On Jan. 10, 1948, at Newcastle-upon-Tyne, to Rebe Monica (née Hastings), M.A., D.Th.P.T., wife of John H. Maughan, M.B., B.S., C.P.H., a son.

Pickard.—On Dec. 15, 1947, at West Kent General Hospital, Maidstone, to Joan and Brian Pickard, of Priory Tower, Priory Park, Blackheath, a second daughter—Celia Jane.

DEATHS

Audré.—On Jan. 5, 1948, James Edward Felix André, M.R.C.S., L.R.C.P., of Highleigh, Sidlesham, Chichester, aged 83.

Chandler.—On Jan. 7, 1948, at a nursing home in Sidmouth, Francis William Chandler, M.B., B.S., late of Woodseals, Sheffield, aged 79.

Eales.—On Jan. 5, 1948, at St. Andrews, Bronhill Road, Torquay, George Young Eales, M.R.C.S., L.R.C.P., aged 88.

Firth.—On Jan. 9, 1948, Arthur Charles Douglas Firth, M.D., F.R.C.P., of 236, Hills Road, Cambridge.

Gleeson.—On Jan. 7, 1948, Olaf Gleeson, M.R.C.S., L.R.C.P., of 10, Harley Street, London, W.

Hulbert.—On Jan. 4, 1948, at Hartley Witney, Joseph George Hulbert, M.B., B.Ch., Lieutenant-Colonel, late I.M.S., aged 80.

Jenner.—On Jan. 7, 1948, at 20, Birchwood Road, Petts Wood, Kent, Wesley John Jenner, M.D., F.R.C.S.Ed., aged 77.

Jones.—On Jan. 9, 1948, at Monkreddan House, Prestwlek, Ayrshire, Arnold Ernest Jones, M.B., Ch.B.

Martin.—On Jan. 5, 1948, at Southampton, Anna Pollock Martin, M.D., M.R.C.O.G., late of Nagpur, India.

Pope.—On Jan. 5, 1948, at 11, Albert Road, Southport, Adolphe Joseph Pope, M.R.C.S., aged 93.

Reade.—At "Riversley," Banbridge, Northern Ireland, Thomas Edwards Reade, M.B., B.Ch.

Selkirk.—On Jan. 5, 1948, at a nursing home, Edinburgh, Elizabeth Thompson Selkirk, M.B., Ch.B.

Stich.—On Jan. 6, 1948, at Kent County Hospital, Pembury, Alexander Benham Stich, M.B., Ch.B., aged 58.

Swan.—On Jan. 7, 1948, at Highgate Hospital, James Herbert Swan, L.R.C.P.I.&L.M., D.P.H., of 22, Dartmouth Park Hill, London, N.W.

Wigmore.—On Jan. 3, 1948, at Hereford, Alfred James Wigmore, M.R.C.S., L.R.C.P., aged 71.

Woodman.—On Dec. 29, 1947, at The Cottage, Avonmouth, Mandeville, Jamaica, B.W.I., William James Woodman, M.R.C.S., L.R.C.P., Colonial Medical Service, retired, aged 75.

Woodward.—On Dec. 29, 1947, at 35, Roker Park Road, Sunderland, Alexander Taylor Woodward, M.B., Ch.B., aged 52.

Woodward.—On Jan. 2, 1948, Henry Martin Mogridge Woodward, M.R.C.S., L.R.C.P.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Treatment of Warts

Q.—*What treatment is suggested for warts on the fingers? Silver nitrate and podophyllin have been unsuccessful.*

A.—Treatment may be radical, by curettage. Many warts are radio-sensitive and clear up with a fractional dose of x rays. Other measures commonly employed may be effective by suggestion. Podophyllin is not helpful in this type of wart.

Hyperplasia of Tonsils

Q.—*What are the pathogenesis, nature, significance, and treatment of the fluid, or cheesy material, often offensive, frequently found in the crypts of the tonsils? There does not seem to be any evidence of inflammation in these cases, but a history of tonsillitis is often elicited. Do such tonsils have a toxic influence? Massage, syringing, and suction of the tonsils do not seem to cure, but a diet poor in starch is helpful. Is there any other treatment short of removal of the tonsils, which the patient wishes to avoid?*

A.—The cause of this condition is hyperplasia of the tonsil, leading to the formation of deep crypts, the orifices of which are narrow or actually occluded. The material which accumulates in these crypts consists chiefly of shed epithelial cells, together with a variety of bacteria, the growth of which causes decomposition of the material. Such bacteria are not necessarily pathogenic, but carriers harbour haemolytic streptococci and diphtheria bacilli in the same inaccessible situation, which accounts for the difficulty of abolishing the carrier state by any means short of tonsillectomy. It seems improbable that the absorption of the contents of such crypts could cause toxic effects; in so far as these are observed they are more likely to result from actual infection of the substance of the tonsil, with or without the acute exacerbations to which these patients are subject.

Tonsils exuding thin pus containing pathogenic organisms may be considered a source of toxæmia; those exuding cheesy material are probably not, in spite of the unpleasant symptoms they produce. In both cases the only effective treatment to secure a permanent cure is tonsillectomy.

Drug Addiction

Q.—*(a) What procedure—therapeutic and/or statutory—should a general practitioner follow when confronted with a case of addiction to a scheduled drug? Can any compulsion be brought to bear on patient or relatives to secure either treatment or responsible supervision?*

(b) A woman aged 30, with three children, has become addicted to pethidine since having injections for attacks of trigeminal neuralgia a year ago. What treatment would you suggest?

A.—*(a)* Addiction to drugs usually implies a morbid craving for one of the opium alkaloids or similar synthetic preparations, or for cocaine or one of its derivatives. This seldom occurs except in persons of abnormal mentality, so that treatment usually requires the services of an expert psychiatrist. It is almost always impossible to treat the patient satisfactorily except in an institution with special arrangements for strict control, to prevent surreptitious supplies of the drug continuing to reach the addict. The general practitioner is seldom called upon to do more than persuade the patient to enter a suitable institution for detoxication and the first steps towards mental and physical rehabilitation. After these steps have been taken a great deal remains to be done to prevent relapse, and here a wise family physician with a strong, sympathetic personality can do more than any specialist. The details of the treatment in the early stages must be adapted to the individual case, and

cannot easily be summarized in a short article—the subject is well dealt with in standard books of reference.

If the patient proves completely uncooperative it may be necessary to invoke the aid of the law to apply compulsion. Since most of the drugs concerned are included in the scope of the Dangerous Drugs Acts, 1920–5, it is often possible to prove an offence against these Acts for which the patient may be summoned before a magistrate. If this be done, and the facts proved, it is open to the Court to bind the defendant over on condition that he enters a suitable institution and follows a prescribed course of treatment, failing which he becomes liable to the heavy penalties, including fine or imprisonment, provided under these Acts.

(b) As in every case of drug addiction, the patient must be admitted to a hospital or nursing-home for the treatment. Withdrawal symptoms of pethidine are, so far as is known, slight and harmless compared with those of morphine. The drug should be reduced by 20% of the addiction dose daily, so that at the end of five days it is discontinued. This should be followed by remedial exercises aiming at producing bodily fatigue. A psychiatrist should be asked to deal with his side of the problem. Return home should not be before three months. Pethidine is now subject to the Dangerous Drugs Acts.

Fat Atrophy due to Insulin Injections

Q.—*In a diabetic woman who has been having 20 units of protamine insulin a day for the past year all the usual sites for injection have become impossible owing to absorption of subcutaneous fat. Has this condition been recognized before, how is it brought about, and what can be done to prevent it?*

A.—The condition was recognized soon after the use of insulin began. The only way of preventing it is to change the type of insulin as soon as the fat atrophy appears and choose the one which causes least damage. The site of injection should always be varied as much as possible, even though the patient is not sensitive to the insulin. Even after fat atrophy has occurred the insulin seems to be well absorbed.

Treatment of Alopecia

Q.—*Is p-aminobenzoic acid effective in the treatment of alopecia? What is the accepted modern treatment?*

A.—There are almost certainly many causes of alopecia, and one may be a deficiency of p-aminobenzoic acid. But there is no indication that p-aminobenzoic acid has any effect on growth of hair, and the evidence that it affects the colour of the hair is contradictory. Alopecia areata is an individual or sometimes a family pattern of reaction to disturbances of health or tone, and treatment turns upon the restoration of health and readjustment. Any general medical treatment is symptomatic, and local treatment is essentially directed towards stimulation of regrowth by counter-irritation, which can be effected by a variety of local applications as detailed in textbooks.

Vitamin B Content of Yeast

Q.—*(a) Does yeast contain all the vitamin B requisites for the body? (b) What quantities should a 10-stone (63.5-kg.) man take daily? (c) Is autolysed yeast better than yeast not so treated? Can I autolyse it myself? (d) Is yeast bought at the local baker's as good as that prepared by adding a pinch of hops and a dessertspoonful of flour to half a pint (284 ml.) of water, sealing, and leaving in a warm place for three days? (e) Should the taking of yeast have any relation to meal-times?*

A.—*(a)* The only vitamins of the B complex that are known to be essential for man are thiamine, nicotinic acid, and riboflavin. Others may be necessary, but there is no clinical evidence of this at present. Yeast contains thiamine, nicotinic acid, and riboflavin. *(b)* It is impossible to say what dose a 10-stone male should take. The vitamin potency of yeast is extremely variable, depending on the source, the strain of the yeast, the medium in which it grows, and its age. The writer has noted only one type of commercially available yeast of declared potency, and this contains approximately 25 mg. aneurin, 7 to 9 mg. nicotinic acid, and 1.4 mg. of riboflavin per ounce (28 g.). Thus 1 ounce daily with the food would provide enough of all the B vitamins, and actually ten times

as much aneurin as is needed. Such yeast can also be obtained in tablet form. (c) Autolysed yeast is best, because only about 20% of the vitamins are available in live yeast. The best plan is to pour boiling water on the yeast to kill the cells before it is eaten. (d) Yeast bought at the local baker's is unsatisfactory as a source of B vitamins, as it is of unknown potency. Thus the aneurin content may vary from 0.03 to 2 mg. per ounce. For the same reason home-made yeast is unsatisfactory. Incidentally yeast cannot be prepared by the method described, which would encourage the growth of many moulds and organisms. (e) From the point of view of absorption of the vitamins, it does not matter whether yeast is taken with meals or not.

Removal of Naevus

Q.—My daughter, aged 11 months, has a naevus about the size of a sixpence on her forehead at the junction of hair and skin. It is slightly raised and rather disfiguring. What is the best treatment?

A.—The naevus would appear to be a superficial cavernous angioma, a strawberry mark, and is likely to disappear spontaneously in the course of a few years. It should readily clear if frozen with a pencil of carbon-dioxide snow for twenty seconds. Unfiltered x rays, 600 r units (60 kV, 4 mA), would also favour gradual resolution, and neither treatment should produce scarring to interfere with hair growth.

Irregular Menstruation

Q.—Is it possible to use stilboestrol in the case of a woman nearing the menopause whose periods are becoming irregular? If so, what is the optimum dosage, and would prolonged administration be dangerous? Is there any risk if the delay is due to pregnancy?

A.—If the only "menopausal" symptom is irregularity of menstruation, treatment with stilboestrol or other oestrogens is rarely, if ever, indicated. If the irregularity takes the form of periods of amenorrhoea, no attempt should be made to re-establish menstruation; whereas if it is characterized by prolonged or heavy bleeding, diagnostic curettage should be carried out. The only possible indication is in those cases where prolonged bleeding has been shown (by histological examination of the endometrium) to be of the "threshold" type. The indiscriminate and prolonged use of stilboestrol at the menopause has real disadvantages. Unless the dose is controlled very carefully it is likely to cause endometrial hyperplasia and heavy bleeding, and in theory at any rate might cause carcinoma of the uterus. Moreover, if such treatment is suspended suddenly, flushes and other manifestations of the menopause may be precipitated. Stilboestrol even in large doses will not disturb a normal pregnancy.

Mixed Diphtheria Toxoid and Pertussis Vaccine

Q.—In inoculation with mixed diphtheria A.P.T. and pertussis vaccine (alum-precipitated) it is recommended that three injections be given at intervals of four weeks. When the patient is not brought up to time, should one anticipate any severe reaction, and is protection adequate with a longer interval between the first and second injections? If a fresh course should be started, what interval should elapse between the first injection of the new course and the first injection of the abandoned course?

A.—It has been well established experimentally that in immunization against diphtheria with A.P.T. the second injection, even if it is given six to twelve months after the first injection, will still elicit a good antibody reaction provided the first dose has been adequate to sensitize or prepare the tissues for response to the secondary stimulus. The risk of any severe reaction is not increased by a long interval between first and second doses, but of course if the second injection is delayed unduly the child in the meantime cannot be regarded as having been effectively immunized against diphtheria. The same principles presumably apply to the use of a mixed antigen of diphtheria toxoid and pertussis vaccine; there is no objection to combining these two antigens, provided each has been shown to be effective separately.

NOTES AND COMMENTS.

Enuresis in Young Adults.—Mr. H. P. WINSBURY-WHITE (London, W.) writes: In the *Journal* of Dec. 20, 1947 (p. 1016), a question is asked in these words: "Can anything be done to benefit chronic enuresis in young adults? In the case I have in mind full neurological and urological examinations have proved negative." The points of fundamental importance in this matter are that what is called a full urological examination commonly omits a urethroscopy, and that young adults with enuresis frequently have a lesion in the urethra, and the appropriate treatment of such a lesion generally results in a marked improvement or a cure of the enuresis. Let me recount the facts of a recent case, a male of 19 years.

At the age of 14 he started bed-wetting two or three times a week, and had one-hourly frequency during the day. At the age of 16 a full urological examination, which included urethroscopy, had been carried out, when the only abnormalities to be found were granulomatous changes on the verumontanum and in the prostatic sinuses, and there was slight narrowing of the whole urethra. As a result of a single urethral dilatation the patient had only two wet beds in the course of the first three months after this treatment. Then he went for the next twelve months without a single wet bed; no further treatment was given during that time. He then began to relapse slowly and further urethral dilatations did not help him. Urethroscopy at the age of 19 showed granulomata still present as before. These I fulgurated two months ago, with immediate benefit the frequency being reduced from one to three hours, and the enuresis to no more than three occasions in five weeks; whereas previous to operation he had been having one or two wet beds every week.

The benefit to the patient's mental state from the improvement he again experienced was certainly a gratifying and interesting feature of the case. This patient will certainly need further supervision and probably more treatment, in which circumstances I consider the prospects good.

Corrections

In our report (Dec. 27, p. 1049) of a meeting of the Section of Otolaryngology of the Royal Society of Medicine, the statement "Mr. Gavin Young said that formerly cases of acute mastoiditis were met with once or twice a year," should have read "cases of latent acute mastoiditis."

In reporting a meeting of the Section of Psychiatry of the Royal Society of Medicine (Dec. 27, p. 1048) some remarks made by the previous speaker were erroneously attributed to Dr. Melanie Kleir. What Dr. Klein actually said was: "In considering the importance of aggression in the emotional life of the infant, we have to give full weight to the fact that aggression, since it is primarily directed against loved people—first of all the mother—gives rise to feelings of guilt and to the drive to make reparation. The tendency to make reparation enters into all sublimations and influences feelings of love and the relation to people. In these ways aggression forms a bridge between hatred and love. Freud pointed out many years ago the importance of the sublimation of aggression and the social effects of these processes. Further work, particularly carried out in the British Psycho-Analytical Society over the last twenty years and based on the psycho-analysis of children, has led to the recognition of the importance of the tendency to make reparation for aggressive impulses and phantasies."

In our obituary notice of the late Mr. G. F. Stebbing (Jan. 2, p. 28) it was stated that he had been "a member and honorary secretary of the Radium Commission from its formation in 1929. We are now informed that this was not the case. Prof. Sidney Rus was Scientific Secretary of the National Radium Commission from 1929 until 1935.

Dr. R. T. BRAIN points out that in his note on "Ringworm of Scalp" (Jan. 10, p. 86) thorium X was written in error for thallium acetate.

B.M.A. SECRETARY GENERAL: DR. J. H. G. ...

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON SATURDAY JANUARY 17 1948

British Medical Association SPECIAL REPRESENTATIVE MEETING

A LEAD TO THE PROFESSION THE IMPENDING PLEBISCITE

On the requisition of the Council a Special Representative Meeting was held in the Great Hall of B.M.A. House on Thursday, Jan. 8. It was attended by 357 representatives of all Divisions and Branches in Great Britain and Northern Ireland, and by some 30 members of Council who were not representatives.

The principal purpose of the meeting was to decide the form of the forthcoming plebiscite, and the greater part of the day was taken up with "procedure" discussions concerning the phrasing of the instructions on the plebiscite form, the shape of the questions, and the size of the majority which should be taken as determining the issue. At the same time, a strong lead was given to the profession in the shape of a "solemn declaration," passed without a dissentient voice, that the Act in its present form "is so grossly at variance with the essential principles of our profession that it should be rejected absolutely by all practitioners."

The documents before the meeting were the Negotiating Committee's statement and the Minister's reply, published in the *Supplement* of Dec. 20, and the Council's statement in rejoinder, published in the *Journal* of Dec. 27.

The Form of the Plebiscite

The Chairman of Council (Dr. Dain) moved that, prior to the issue of the plebiscite, the Representative Body should indicate to the profession the minimum size of majority which would justify the Association in recommending the profession not to accept service under the Act in its present form. He said that it was desired to avoid argument afterwards as to whether the majority obtained justified the taking of action. If it was known beforehand that a substantial majority was required—a majority of a stated size—each member of the profession would have more certainty in casting his vote. An amendment was moved by North-east Essex that no plebiscite should be taken until the terms of service were fully known. The chief reason behind the amendment was that consultants as yet did not know on what basis they would be expected to work; general practitioners, too, desired more knowledge.

Many representatives spoke in opposition to the amendment, and when it was put to the meeting scarcely a vote was given in its favour. The Council's recommendation was carried. The meeting then turned to the discussion of the effective majority. The Council's recommendation was as follows:

That it be made clear on the plebiscite form: (1) That if in the aggregate of the votes of consultants and specialists (not holding whole-time salaried posts) and general practitioners there is a majority against accepting service under the Act, and this majority includes approximately 13,000 general practitioners (this represents 63% of all general practitioners), the Association will advise the profession not to enter into any contract under the Act in its present form, but to continue their services to patients or other professional

work. (2) That, if these majorities are not achieved, practitioners who undertake not to enter the Service will be released from such undertaking.

The Chairman of Council said that this had been considered at great length by the Council. The votes of those directly implicated—chiefly the clinical people, namely, consultants and specialists and general practitioners—would be counted separately, and a majority would be required in the aggregate of those groups. Further, before action was taken a certain specified majority of general practitioners would be required. The Minister could not possibly set up a service for the whole country with fewer than 8,000 practitioners, and it was felt that if a minimum of 13,000 general practitioners voted against service the majority should be considered sufficient.

A long discussion then ensued on the question of the different categories in the profession who might be requested in the plebiscite to say, not only whether they approved or disapproved of the Act in its present form—a question which every member of the profession is expected to answer—but also whether they were or were not in favour of accepting service and whether they agreed or did not agree to abide by the decision of the majority not to undertake service if the requisite majority was obtained and if so advised by the B.M.A. It was pressed by Marylebone that in addition to general practitioners and consultants and specialists who did not hold whole-time salaried posts, a number of whole-time people should be included in the aggregate.

The Secretary (Dr. Hill) pointed out that the important thing was to know the proportions of those in the various branches of the profession who would be confronted with the personal issue of joining the Service. Apart from consultants and specialists in private practice and general practitioners, the most important group seemed to him to be the voluntary hospital residents, and the case for including them seemed to be fully established.

After further debate it was agreed that those who should be requested to answer the second and third questions in the plebiscite relating to acceptance of service, and whose votes would count in the aggregate mentioned in the motion, should be extended to include consultants and specialists holding whole-time salaried posts and the holders of whole-time appointments in voluntary hospitals.

The Effective Majority

Several proposals were on the paper to increase the percentage majority required to justify advising the profession not to enter into any contract under the Act in its present form. It was pointed out that the higher the percentage aimed at the more likely was it to be achieved. The Isle of Wight representative (Dr. Howie Wood) said that the first reaction of the four study groups in his Division was that 63% was too low a figure, but later they began to feel that the Council, with all the information at its disposal, would not have chosen a figure without a good basis for it, and that 63% must have been selected with a full understanding of many factors of which nothing was known at the periphery.

The Chairman of Council hoped that the meeting would not be led into altering the figure the Council recommended, but

it must not be assumed that the Council wanted only 13,000 general practitioner votes; it wanted 20,500. The figure 13,000 was a minimum, the result of taking all the circumstances into consideration. It represented roughly 63% of the whole field, and if there was an 80% vote—he hoped for a much higher vote—the 13,000 would represent 80% of the vote. He went on to remind the meeting that action did not begin or end with the signing of a plebiscite form. He had had a number of letters suggesting that there be embodied in the form a legally binding document pledging the signatory not to accept service in certain eventualities. This, however, could not be done consistently with the undertaking that the individual vote would not be divulged. But when the figures were known it would be for the doctors themselves to make agreements, not with the B.M.A. or with the profession but with each other in their own neighbourhoods.

The Council's figure of 13,000 general practitioners was agreed to, but it was agreed also to delete any reference to a percentage, which might confuse the minds of some people, from the plebiscite form, and to relate the figure of 13,000 to the present total general practitioner strength of 20,500.

The effect of these modifications of the Council's recommendation is that it will be made clear on the plebiscite form

(1) that if in the aggregate the votes of consultants and specialists, general practitioners, and whole-time voluntary hospital staffs show a majority against accepting service under the Act and this majority includes approximately 13,000 general practitioners (out of a present total general practitioner strength of 20,500), the Association will advise the profession not to enter into any contract under the Act in its present form, but to continue their services to patients or other professional work;

(2) that if these majorities are not achieved, practitioners who undertake not to enter the Service will be released from such undertakings.

The Vote of the Consultants

An amendment from Sunderland was proposed, the effect of which would have been to make action on the plebiscite dependent on the votes of general practitioners alone, leaving out consultants and specialists. The mover (Dr. D. R. Cramb) said that, in the northern area at any rate, consultants and specialists were rather unhappy because they did not know where they stood. To ensure a good plebiscite return the danger of leaving any section of the profession in a state of uncertainty must be avoided. Until consultants and specialists were in a position to make a firm decision they should not be asked to vote—certainly not to vote alongside general practitioners, who had so much more material for arriving at a decision.

In reply it was pointed out that the mandate to the Council from the Representative Body was to take a plebiscite of the whole profession; that this amendment, if accepted, would weaken the resistance of consultants and specialists, and one speaker described it as a "tinker's cuss" amendment, which said in effect that they should concentrate on general practitioners and not care "two hoots" about the rest. Two representatives from Marylebone spoke emphatically against it. Mr. Lawrence Abel: "If the consultants cannot stick by their general practitioner colleagues and realize the implications of this Act, then their blood be upon their own heads." Mr. Dickson Wright: "To leave out the consultants and split the profession into two groups would make it all the easier for the Minister and all the harder for the profession." The amendment was withdrawn.

Certain variations in the proposed wording of the instructions and questions on the plebiscite were put forward with a view to obtaining greater clarity; some were rejected, and others referred to the Council for consideration. Some representatives wanted such advice included as "Attend a meeting in your Division before voting," or "Consult your colleague before voting," but these were turned down. It was felt that the instructions should be as formal as possible. It was mentioned that there would be sent out to members of the profession, separately from the forms, a statement containing full information on the position, and also another document setting out the points in disagreement and the arguments concerning them.

A Solemn Declaration

The procedural business having been disposed of, the following resolution was proposed by Dr. A. C. E. Breach (Bromley) and accepted by the Chairman of Council:

The elected representatives of the medical profession in Great Britain and Northern Ireland meeting in London this eighth day of January, 1948, solemnly declare that in their considered opinion the National Health Service Act, 1946, in its present form is so grossly at variance with the essential principles of our profession that it should be rejected absolutely by all practitioners.

This was carried immediately and without discussion, and no hand was raised against it. It was understood that this declaration would appear on the documents, other than the plebiscite form itself, sent out to the profession.

The passing of this declaration made unnecessary a motion by Marylebone calling for the strongest possible lead to the profession not to accept service under the Act, but the motion was briefly discussed.

Continuance of Medical Services

The Gateshead Division asked that immediate consideration be given to the steps to be taken to continue medical services should service under the Act be refused on July 4. The mover, Dr. J. C. Arthur, said that in his Division there would be no difficulty because they had a large and efficient Public Medical Service, but all areas were not so fortunate. The Chairman of Council said that this problem had given the Council serious thought. Where there was a public medical service it should be offered, though, of course, there could be no compulsion on patients. It was well to remember that the crisis was not likely to be long drawn out, and he could not foresee any great difficulty in the way of most practitioners carrying on their practice as they did to-day. He thought there was no alternative except to go on doing what they were doing as the preamble on the plebiscite form said, they would "continue their services to patients or other professional work."

The Gateshead motion was carried. In reply to the representative of North Staffordshire, the Chairman of Council said that if and when they came to an agreement with the Government they would, of course, insist that there must be no victimization. In reply to the representative of Darlington he said that the Executive Committee was meeting before the end of the month to decide on forms and methods whereby a practitioner might refuse service and remain confident that he would not be "let down" by other practitioners.

The meeting concluded with enthusiastic votes of thanks to the Chairman of Council and to the Chairman of the Representative Body (Dr. J. B. Miller), who had presided with his customary skill and humour throughout the day.

NORTHERN IRELAND HEALTH BILL

The Minister of Health and Local Government in Northern Ireland, Mr. William Grant, M.P., gave a Press conference this week during his short stay in London, where he has been visiting Mr. Bevan and other Ministers. Mr. Grant said that it was the declared policy of his Unionist Government to maintain the social services of the country on the same level as that obtaining for the rest of the United Kingdom. In pursuance of that policy a Bill was now passing through Parliament to provide a comprehensive health service available for all sections of the community. When the proposals came into operation—which he hoped would be on July 5—the people of Northern Ireland would be entitled to the same health service benefits as those provided in Great Britain under the recent Act. The Bill had passed through all its stages in the House of Commons and would be before the Senate this week. Notwithstanding 500 amendments on the paper a fairly good agreement had been reached between the different parties.

Asked whether the Bill had the support of the medical profession in Northern Ireland Mr. Grant said he would not claim that it had their entire support, but they were friendly with his Ministry, and he thought, by and large, that the Bill had their general approval. The hospital position, too, with the

proposed co-ordination of voluntary and local authority hospitals, was satisfactory, and the Cabinet had even received a letter of thanks from the representatives of the hospitals. In reply to a question as to how the Bill compared with the Act already passed by the British Parliament, Mr. Grant said: "We are not going up the same street, but we shall arrive at the same place, I hope, in the end."

Freedom of Doctors

In the arrangements with practitioners no basic salary was proposed, except in rural districts where the numbers on a doctor's list might not afford him a reasonable income. The capitation method of remuneration was the Government's policy, but of course rates of payment had not yet been discussed. There was no direction of doctors. "We fought for liberty, and we maintain it." The Bill provided for appeal to the courts against dismissal from the Service. "As Minister I do not want any trouble I can avoid." He added that there was provision in the Bill for health centres, but this was a question of obtaining building material, which is scarce in Northern Ireland even for ordinary houses.

Mr. Grant said that his country suffered from a nursing shortage; it had not been necessary to close down any hospital wards for lack of nurses, but the opening of extensions had been held up. The Ruschcliffe scale had been adopted. He spoke with pride of the creation in 1946 of the Northern Ireland Tuberculosis Authority, which replaced the former eight county committees. The authority consisted of thirteen representatives of local authorities and four nominees of the Minister, and had power to co-opt. Its duties covered the whole field of tuberculosis from prevention to after-care. The Act under which the authority operates is regarded in some quarters as the foremost piece of legislation on tuberculosis in the United Kingdom. Maternity and child welfare, blood transfusion service, and health education are in the Ministry's general programme of reorganization and improvement.

has been suggested which it is thought will materially reduce the number of such examinations and to that extent relieve the doctor of the necessity for visiting the proposer.

This procedure, which has been accepted for a trial period of twelve months, and which will take effect as from Jan. 1, 1948, is as follows:

- (i) That it shall be an instruction to Agents and District Managers of the Industrial Assurance Offices that, whenever possible, arrangements shall be made for the examination to take place at the practitioner's surgery.
- (ii) That, where this is impracticable, authority for the practitioner to be requested to make a domiciliary examination must be obtained from the Head Office or Regional Office of the Company or Society.
- (iii) Where such authority is obtained, mileage shall be paid at the rate of 1s. per mile or part of a mile, each way, beyond a radius of two miles from the practitioner's surgery.

B. Commencement

The terms of the new Agreement supersede those of the Agreement of 1920.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

County Borough Councils.—Gateshead.

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Leyton, Radcliffe (limited to future appointments), Tottenham, WallSEND.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Stanley (Co. Durham), Tyldesley.

Scottish Burghs.—Motherwell and Wishaw.

HEARD AT HEADQUARTERS

FEES FOR LIFE ASSURANCE MEDICAL EXAMINATIONS

The attention of members is drawn to the terms of the new agreement in regard to fees for life assurance medical examinations which has been reached as the result of discussions with the Life Offices' Association, the Associated Scottish Life Offices, and the Industrial Life Offices' Association.

A. Forms Used for Medical Examination

There will be two types of form, as follows, both of which will bear a note of the appropriate fee payable.

1. *An Office's Ordinary Form.*—This will be used in all cases where the amount of the proposed sum assured exceeds £300, and may be used for smaller cases if the Office so desires. The fee for the examination and report on this form will be £1 11s. 6d.

2. *A Short Form.*—This may be used in all cases where the amount of the proposed sum assured does not exceed £300, as stated on the form. The fee for the examination and report on this form will be 10s. 6d. This special short form has been standardized and, apart from the questions answered by the Proposed in the Doctor's presence, will contain the following questions:

- (a) Does the Proposed appear in good health? Is his/her appearance consistent with the age stated?
- (b) Is there any reason to suspect irregular or intemperate habits?
- (c) Are there any abnormalities of the heart or lungs or pulse?
- (d) Are there signs or symptoms of kidney disease? Result of urine examination. Albumin..... Sugar.....
- (e) Height of the Proposed. Weight of the Proposed. (If possible the Proposed should be weighed and measured by the Examiner.)
- (f) Are there any other circumstances not covered by the questions with which the Company should be acquainted? (e.g.: In female cases, is she in an obvious state of pregnancy?)
- (g) In which of the following classes would you place the risk—First, Second, or Third?*

Domiciliary Examinations.—The more usual practice is for examinations to be made at the surgery, but circumstances arise where this is not convenient to the proposer and certain procedure

* Classification: First Class, lives acceptable on ordinary terms; Second Class, assurable, but only on special terms; Third Class, unassurable.

The Octopus

The Public Relations Department of the Association has got out a most effective folder, the principal feature of which is a pictorial design illustrating the arrangements under the new Act. The picture, which is in colours, admirably done by F. K. Henrion, the distinguished poster artist, well conveys the strong jaws and unattractive countenance (officially, of course, not personally) of the Minister of Health, while his sucker-bearing arms hold all the things which he can determine—by regulation, appointment, provision, control, approval, whatever it is—in relation to hospitals, general practice, and local authority services. For example, in general practice it is shown that he controls entry into the public medical service through the Medical Practices Committee; that he regulates the Executive Council, which consults the Local Medical Committee, and contracts with the general practitioner; also that he appoints the Central Health Services Council and controls dismissal from public medical practice through a tribunal. There is more in the design than meets the eye—and the eye has quite a lot to meet it. It is said that on occasion the octopus will devour its own arms, which may, for anything we know, be the fate of these appointed or approved bodies. The folder, which includes a number of other facts tersely set out, is being sent to every member of the profession, and in a larger size it is available on application for exhibition at divisional or other meetings.

First Shots

Dangerous as it is to infer too much from mass meetings, no one could have gone away from the first such meeting in London or the one held a day or two later for Surrey practitioners at Wimbledon without feeling strongly that the profession was of one mind. The Great Hall of B.M.A. House, had it been twice as large, would still have been comfortably filled. The meeting was with the speaker, the Secretary of

the Association, and advanced with him from point to point in his devastating analysis of the Minister's reply. Perhaps it was a pity that it was a case of preaching to the converted (no sign of dissent was perceptible, except perhaps in the tenor of one question), but the converted were sufficient in number to do some useful converting on their own account if such is needed. The unanimity of feeling was impressive. Perhaps this time the oratorical advantages are with the profession; last time, with Lloyd George as spellbinder, they were on the other side.

Misleading Parallels

Reference to Lloyd George reminds one who in a very humble capacity went through all that controversy thirty-five years ago that history, when all is said and done, never repeats itself. There are points of coincidence, but when the pattern is examined the points of difference far exceed them. Take, for example, the voting of the profession in 1912 on the question of accepting service under National Health Insurance (it was not called a plebiscite in those days). In 1911 there were 27,400 signatories to the B.M.A. pledge, but when, in December, 1912, another vote was taken, although there was an overwhelming majority against acceptance of service—something like 11,200 to 2,400—only half the previous signatories voted at all. And why? Simply because in the meantime the Chancellor had threatened that if the profession refused service he would institute a whole-time salaried State medical service. This time no practitioner will withhold his vote because of that fear. A whole-time State medical service is not threatened, it is at the very door, and the only thing that can avert it is a vote in the plebiscite.

Principles Not Conceded

The circumstances of 1912 are very different from those of 1948 in other respects. For one thing, the agitation against National Health Insurance was supported by noisy and often ill-advised demonstrations by other sections of the community. Servant girls twice packed the Albert Hall to protest against their mistresses being compelled to lick stamps. Farmers and dockers were aroused. It was made a party political matter. The Government suffered at by-elections. The popular press, for various reasons, ranged itself against the measure. The doctors, in spite of their good case, found themselves in some rather unusual company. This time, while it is believed that the profession can count on the sympathy of the public, it is the profession's fight, and that is all to the good. Most important of all, last time, when it came to the point, the profession had already gained its principles, and practically the only matter that remained was a quarrel over the size of the capitation fee. Free choice of doctor and other things had been conceded. Perhaps that also helped to swell the 50% of non-voters. This time no one will withhold his vote on the ground that anything has been conceded. There may be a certain amount of argument about the adequacy of remuneration, but the real fight is on principles not one of which, in spite of months of patient argument, has been conceded. Indeed, events are not running parallel with 1912; they are running in the opposite direction.

Quieter Problems

While the energies of the Association are occupied with medico-political questions other work continues. Two committees in particular have been busy as the New Year opens. One is the newly appointed committee on nutrition, which has a bulk of literature in front of it enough to occupy it for a month, and has split up into subcommittees to study the material. The other is the committee on nursing, which at its second meeting received a report from its subcommittee on the training of nurses. The subcommittee, which like the main committee has as its chairman Dr. Mary Esslemont, of Aberdeen, has brought forward a training scheme which will go as a recommendation to Council. The scheme would require all candidates for nursing training to complete a pre-clinical course before undertaking hospital training. The two periods—the preclinical and the basic hospital training of a practical character—would together cover a period of two

years. For students proceeding beyond the basic hospital training there would be a third year's course leading to a qualifying examination for State registration. Students who complete the basic training but do not undertake the third year's course would, after a practical examination, be given a status with some such name as "auxiliary nurse." The term "assistant nurse," because of its present connotations, will be avoided.

Correspondence

Medical Records

SIR,—I note in the report of the meeting of the Insurance Acts Committee (Dec. 27, 1947, p. 168) that the Ministry of Health is seeking to destroy the medical records of all who have ceased to be entitled to N.H.I. medical benefit. Presumably one can expect no better from such an organization and must conclude that housewives and those whose income has been raised above N.H.I. limits are among those who do not matter "a tinker's cuss" to His Majesty's Government. I had, however, expected better of the Insurance Acts Committee and was horrified to read that "several members of the committee expressed the view that an effort should be made to prevent the destruction of these records, but eventually it was decided to ask that current records should not be withdrawn from doctors, the Ministry being left to make the decision regarding old records."

May I point out to the majority of the Insurance Acts Committee responsible for this decision that whatever may be their own practice it is the custom of some doctors to keep full and accurate clinical records. If they are sent for pulping *en masse* it will be an act of the grossest negligence by those who have assumed responsibility for the health of the nation, and we shall have acquiesced in it. It is essential for the efficient running of the new Service that the records in question should remain available, and I submit that this is a point of far more importance than many on which the B.M.A. is ready to take issue with the Minister. In this connexion it would be interesting to know what is the policy of the Ministry of Health with regard to its own records. I think it will be found that the Ministry regards its most trivial administrative communications as more important than the entire medical history of any patient.

Since the I.A.C. have failed us I must ask the profession as a whole to take some notice of the danger which threatens. The matter must be put most forcibly to the Minister, and if no satisfactory reply is received the profession itself must arrange to care for the records. Micro-filming is a possibility which would at least avoid permanent loss, but far better would be the retention of the actual record until it could be incorporated in the N.H.S. record.

It seems that the B.M.A. as a whole might undertake a service of this nature, and that it should not be restricted to N.H.I. notes but should extend to any medical records which are presenting a problem in storage to their present custodians—e.g., the private records of deceased or retired doctors, mass radiography films, completed school medical records, etc. The filing service would issue any record to the practitioner in charge of the patient on condition that it was not destroyed by him and that it was returned to the filing service or made available to any succeeding doctor when no longer required. With certain safeguards they could also be made available to research workers.

All this would cost money and take up office space and clerical labour, but not nearly as much as is used for many much more trivial purposes. And it would be well worth doing if it could answer such questions as, "Was the tumour removed ten years ago proved histologically to be malignant?"

—I am, etc.,

Silver End, Essex.

J. W. NICHOLAS.

Joint Tuberculosis Council

SIR,—Few will be likely to disagree with the views expressed by Drs. D. P. Sutherland and N. J. England in their letter (Dec. 27, 1947, p. 171) concerning the necessity for clinical teams and for a regional administrative tuberculosis officer to co-ordinate the services provided. Many will welcome the

recommendations (Nov. 1, 1947, p. 100) that tuberculous patients should be looked after by specialists (physicians) in charge of clinical teams and sanatorium physicians of a "status identical with that of other consultants." But a point not explained is how such specialists will in fact be of the status described and yet subordinate to a regional tuberculosis physician—a higher specialist officer—unless of course the Joint Tuberculosis Council considers that all consultants will be expected to work under the regional consultant officer of their specialty. It may all depend on what is meant by "identical status," but surely these words have a very definite meaning.—I am, etc.,

Kenton, Middlesex.

H. J. TRENCHARD.

Working Conditions for the General Practitioner

SIR,—May I as a very junior G.P. be allowed to support Dr. W. E. R. Branch's very apt remarks (Dec. 27, 1947, p. 171)? I took over this single-handed practice of medium size 12 months ago, and if I was not deeply committed I would gladly forsake it as soon as possible. It has been 12 months of near slavery for both my wife and myself, and no matter how difficult things were 30 years ago the previous generation of G.P.s had few of our present difficulties to face.

There are in this small town some 10 medical practices—all well established and all, bar two or three, have partners or assistants, mine being the only practice where there is no arrangement for off-duty, not even one day per month. My opposite number has both a partner and an assistant, but I can come to no definite agreement with him. You may say that this is due to lack of personality on my part, but even if this is so it is the patient who suffers if the doctor is tired and has no opportunity for relaxation.

I feel as Dr. Branch does that the fear of competition prevents co-operation. Any health service that is truly nationalized must prevent such an anomaly. If all the doctors in this area had an equal number of patients and received an adequate basic salary plus extra for age and experience, then the problem would be near solution. If one's professional career is to be based on the number of patients one can cram into the day, then the outlook is pretty dull.—I am, etc.,

WORKMAN.

Regional Hospital Association

SIR,—At a meeting held in Liverpool on Dec. 21, 1947, which was attended by 64 doctors from all parts of the region that is to be covered by the Liverpool Regional Hospital Board, it was decided to form a Liverpool Regional Hospitals Medical Association.

The objects of this newly formed body are: (1) The establishment and maintenance of high standards of efficiency in the hospitals of the Region. (2) The promotion of the professional interests of the members.

The members shall be registered medical practitioners who hold, or have held, positions above the rank of house officer in hospitals and whose main professional interest is centred in hospitals to be administered by the Regional Hospital Board.

The following committee was elected: Chairman, Dr. H. H. MacWilliam; Vice-chairman, Dr. D. W. C. Tough; Secretary, Dr. V. Cotton-Cornwall; Treasurer, Dr. O. F. Thomas. Committee: Drs. R. L. D. S. Derham, R. J. Keating, D. Osborne Hughes, G. Williamson, H. Alstead, R. E. Kemp, T. Stanley Rogers, W. N. Chisholm, L. Findlay, D. Shute, C. M. Vaillant. Messrs. J. A. Martinez, H. L. Davies, L. J. Temple, P. N. Simons.

The Secretary was instructed to inform the B.M.A. and other medical societies concerned, and also the medical press, of the formation of this association. The subscription is 10s. per annum. It is hoped that all who are eligible and were unable to attend will join at once, and that other Regions will organize along similar lines.—I am, etc.,

Liverpool.

V. COTTON-CORNWALL.
Hon. Secretary

Mrs. H. Evans, J.P., member of Cardiff City Council, has been appointed to the Welsh Regional Hospital Board to fill the vacancy caused by the resignation of Alderman T. J. Kerrigan owing to ill-health.

B.M.A. LIBRARY

H.M. Forces Appointments

ROYAL NAVY

Surgeon Rear-Admiral A. E. Malone, C.B., K.H.P., has been placed on the Retired List.

Surgeon Captain A. W. North, O.B.E., has been placed on the Retired List.

Surgeon Commanders S. G. Weldon, E. B. Pollard, and R. G. Anthony to be Surgeon Captains.

Surgeon Lieutenant-Commander S. D. Mosse (R.N.V.R.) has been transferred to the Royal Navy in the rank of Surgeon Lieutenant.

Temporary Surgeon Lieutenant T. A. O'Halloran (R.N.V.R.) has been transferred to the Royal Navy.

ROYAL NAVAL VOLUNTEER RESERVE

Surgeon Commander G. McCoull, O.B.E., V.R.D., to be Surgeon Captain.

Surgeon Lieutenant-Commander P. G. C. Martin, V.R.D., to be Surgeon Commander.

T. S. Eimerl, D.S.C., to be Surgeon Lieutenant-Commander.

Temporary Surgeon Lieutenant J. M. Lees, has been transferred to List 1 of the permanent R.N.V.R.

Temporary Acting Surgeon Lieutenants J. D. Wallace, J. L. Pring, R. M. L. Weir, R. D. Price, P. I. Rutherford, H. F. Hills, R. M. Dooley, J. E. Pitts, J. M. Cliff, C. M. Flood, C. F. G. Prudeaux, T. A. O'Halloran, A. A. R. Meek, A. J. Ogg, D. A. N. Druy, K. A. Newton, T. D. Hanratty, P. H. Hewitt, P. K. A. Andrews, and H. M. Rodger to be Surgeon Lieutenants.

Temporary Acting Surgeon Lieutenant P. T. Clover to be Temporary Surgeon Lieutenant.

Probationary Temporary Acting Surgeon Lieutenants D. J. Rodger, D. A. Arthur, J. L. F. Wyllie, G. A. Carnahan, J. Watt, R. N. Andrew, R. H. Etherington, J. M. Wilks, T. Stratton, M. K. Quinn, W. R. R. Thurstfield, R. H. B. Mills, J. M. O'Brien, P. D. A. Durham, W. A. Heaton Ward, and D. G. Dalglish to be Surgeon Lieutenants.

ARMY

Colonel (Acting Major-General) (now Major-General) W. E. Tyndall, C.B., C.B.E., M.C., late R.A.M.C., to be Temporary Major-General.

Colonel (Temporary Major-General) J. R. N. Warburton, M.C., late R.A.M.C., having reached the age for retirement is retained on the Active List supernumerary to Establishment.

Colonel R. F. Walker, C.B.E., M.C., late R.A.M.C., has retired on retired pay and has been granted the honorary rank of Brigadier.

Colonel F. C. Chandler, M.C., late R.A.M.C., having attained the age for retirement is retained on the Active List supernumerary to Establishment.

Colonel C. Popham, O.B.E., late R.A.M.C., has retired on retired pay.

Lieutenant-Colonel V. J. Bonavia, late R.A.M.C., to be Colonel.

Lieutenant-Colonel W. C. Mackinnon, R.A.M.C., to be Colonel.

Lieutenant-Colonel J. C. Collins, O.B.E., from R.A.M.C., to be Colonel.

ROYAL ARMY MEDICAL CORPS

Lieutenant-Colonel G. G. Drummond has retired on retired pay and has been granted the honorary rank of Colonel.

Lieutenant-Colonel T. E. B. Beatty has retired on retired pay on account of disability.

Lieutenant-Colonel H. P. Rudolf, M.C., has retired on retired pay. Major (War Substantive Lieutenant-Colonel) C. W. Crimmin, O.B.E., to be Lieutenant-Colonel.

Majors R. St. J. Lyburn, J. W. A. McIver, and R. T. Shipman to be Lieutenant-Colonels.

Major J. L. O'Neill, from I.M.S./I.A.M.C., to be Major.

Major C. E. L. Harding, retired and re-employed, has been restored to the rank of Lieutenant-Colonel, on ceasing to be re-employed.

Captains D. J. R. McConvell, W. M. McCutcheon, and J. P. Baird to be Majors.

Short Service Commission.—Lieutenant J. Batchelor to be Captain.

TERRITORIAL ARMY

ROYAL ARMY MEDICAL CORPS

Colonel R. I. Poston, T.D., to be Honorary Colonel No. 7 (Western) General Hospital.

Captain (War Substantive Major) A. M. Robertson, O.B.E., to be Major.

St. Andrew's University Contingent, Medical Unit.—Second-Lieutenant J. J. A. Reid, from Senior Training Corps, Infantry Unit, to be Lieutenant (supernumerary).

TERRITORIAL ARMY RESERVE OF OFFICERS: ROYAL ARMY MEDICAL CORPS

Majors A. M. Robertson, O.B.E., and W. E. Orchard, T.D., from Active List, to be Majors, retaining their present seniority, and have been granted the honorary rank of Lieutenant-Colonel.

Major A. C. M. Savage has relinquished his commission on account of disability.

Captain O. C. Wilkinson, from Active List, to be Captain, retaining his present seniority, and has been granted the honorary rank of Major.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

War Substantive Captains J. E. Lovelock, H. R. Heldt, A. Lederman, D. Jerome-Newman, and D. M. Thomson have relinquished their commissions and have been granted the honorary rank of Major.

War Substantive Captain M. G. Sanyal has relinquished his commission on appointment to a permanent commission in the I.A.M.C.

War Substantive Captains A. F. Shpetner, F. M. Liebmann, E. Rosenbaum and M. H. Kerby have relinquished their commissions and have been granted the honorary rank of Captain.

Short Service Commission, Specialist.—War Substantive Captain A. A. Shcin has relinquished his commission and has been granted the honorary rank of Major.

Lieutenant J. Corbett to be Captain.

War Substantive Captains B. B. Jacobs and S. A. Hossain have relinquished their commissions on account of disability and have been granted the honorary rank of Captain.

Lieutenants A. G. Leatham, M. A. Caldwell-Nichols, W. Stevenson, D. Rivers, K. M. Chalmers, W. Frain-Bell, A. C. Connell, R. P. Bradshaw, P. G. S. Beckett, K. F. Barrett, J. H. Bruce, A. V. G. Bibby, D. J. Dooley, H. W. Donaldson, W. M. Foreman, E. A. Fairburn, J. Flint, J. G. Gould, I. W. Kerr, P. Jewsbury, T. Menzies, D. B. Price, A. E. P. Swinson, J. W. Stewart, P. H. Tribe, G. J. E. Wood, E. C. J. Millar, J. I. Wand-Tetley, A. Feldman, A. Ansell, T. P. Burton, C. Brown, E. Burman, A. R. Cini, J. Cran, R. A. Denham, B. V. I. Greenish, L. S. Goodhardt, J. G. P. Hutchison, E. H. Heilpern, J. H. Johnston, D'A. Kok, D. Lawrence, W. Niman, E. T. O'Dwyer, W. R. Probert, W. L. G. Quintilian, L. L. Ralph, G. Robins, E. W. N. Trounson, M. P. Winstanley, W. Whiakier, J. P. Smith, A. D. Bingham, J. R. G. Bastable, K. R. Brookes, K. B. Chambers, J. I. Cohen, D. J. Crockett, P. L. H. Davey, P. J. Dwyer, J. B. Eades, D. J. Gardner, J. P. Graham, K. C. R. Halliday, R. H. Hansell, R. E. A. Hansen, J. M. Holmes, D. A. L. Jones, O. G. Jones, D. W. W. Jones, H. Keidan, I. A. Kellock, R. J. Kleinclass, A. H. Levy, F. D. Lumb, H. Mackenzie, A. MacLennan, P. M. C. Mark, D. G. Maurice, K. R. Ogilvie, H. Reiler, A. R. Semner, W. A. L. Thompson, J. C. Whildam, R. Wolfson, and D. L. Woolf to be Captains.

Lieutenant R. F. C. Van Cauwenberghé has relinquished his commission.

To be Lieutenants: J. K. Baird, H. Baker, E. Barnett, F. A. Beak, T. L. Begg, J. Black, P. S. Brown, G. O. Clark, B. O. Clements, D. C. Cockburn, J. T. Crean, R. R. De-Mowbray, J. H. Fox, E. J. Gow, P. Hampson, D. G. Hardy, G. Hird, J. B. Howard, D. A. Jack, E. Jones, S. Kalinsky, J. L. Kilgour, J. B. Lawson, C. Levin, J. M. Loughran, G. I. Lumsden, D. H. McMillan, A. W. Morrow, C. D. R. Pengelly, R. L. Richards, J. B. Ritchie, M. J. Roper-Hall, B. Ruebner, I. W. Sinclair, C. R. B. Stewart, R. G. Stewart, T. Symington, B. Towers, J. K. B. Waddington, R. J. S. Weir, H. M. White, and E. E. Vella.

Association Notices

Branch and Division Meetings to be Held

DERBY DIVISION.—At Derbyshire Royal Infirmary, Tuesday, Jan. 20, 8.15 p.m. Mr. R. L. Flett: Ear, Nose, and Throat Cancer. Mr. F. G. Hollands: Genito-urinary Cancer.

GREENWICH AND DEPTFORD DIVISION.—At Miller Hospital, Greenwich Road, S.E., Wednesday, Jan. 21, 9 p.m. Discussion on the Plebiscite.

HYDE DIVISION.—At Dukinfield Town Hall, Wednesday, Jan. 2, 8.30 p.m. Dr. J. S. Parkinson: Recent Advances in Neurology.

WESTMINSTER AND HOLBORN DIVISION.—At City Hall, Chancery Cross Road, London, W.C., Thursday, Jan. 22, 8 p.m. Mr. P. I. Mitchiner: Recent Advances in Surgery.

WINCHESTER DIVISION.—Sunday, Jan. 25, 11 a.m. General meeting. Dr. D. P. Stevenson (Assistant Secretary, B.M.A.) will speak. A medical practitioners in the area of the Division are invited.

WORCESTER AND BROMSGROVE DIVISION.—At Worcester Shire Hall, Sunday, Feb. 1, 2.30 p.m. Address by Dr. H. Guy Dain: The Plebiscite. Open to all members of the medical profession.

Meetings of Branches and Divisions

DUMFRIES AND GALLOWAY DIVISION

At a meeting held in Dumfries on Dec. 21, 1947, Dr. Rob McWhirter, Director of the Radiotherapy Department of the Royal Infirmary, Edinburgh, gave an address on "The Scope of Radiotherapy in Malignant Disease." He pointed out that the use of radiotherapy in the treatment of malignant disease had been greatly extended in recent years. If only cases, which cure was attempted were considered, radiotherapy could alone or in combination with surgery was used in approximately 85% of cases. The incidence of malignant disease was 24 new cases per annum per million of the population, and this number approximately 1,700 died from malignant disease. Differential diagnosis, while easy in the late stages, was of impossible in the early stages unless special methods of examination (histological, radiographic, biochemical, etc.) were employed. An appropriate special method of examination could often be selected only by the specialist. Closer liaison between the specialist and general practitioner was essential, and it was to be hoped that establishing regional medical services provision would be made this.

KENT BRANCH

The Branch Council met at Maidstone on Jan. 2. A full and useful discussion on the proposals under the National Health Service Act, the B.M.A. statement, and the Minister's report took place. The circumstances and action to be taken in relation to the approaching plebiscite were given detailed consideration. Reference was made to the fact that many alien doctors (of whom it was understood there were some 3,000) might apply to enter the Service, but there was the possibility that the majority would decide to accept the final decision of the B.M.A.

MORPETH DIVISION

A meeting of the Morpeth Division was held on Dec. 12, 1947. The Secretary reported that the Branch Council had approached the National Coal Board in connexion with the question of insurance certificates, and a courteous reply had been received, but the decision of the Board had not yet been made known to the Council.

Prof. F. H. Bentley then addressed the meeting on "Changes in Trends in Modern Surgery." His talk, which was particularly interesting and informative, was illustrated with lantern slides and gramophone record. Dr. Stephenson proposed the vote of thanks to Prof. Bentley, and this was most heartily given.

WEST BROMWICH AND SMETHWICK DIVISION

A meeting of this Division, to which all practitioners in the area were invited as well as members of the Dudley Division and Walsall Division, was held on Jan. 4. General practitioners, public health officers, members of hospital staffs, consultants, and others were present. Dr. A. Ward addressed the meeting, and there was a prolonged discussion. Member after member severely criticised Mr. Bevan's scheme, and at last Dr. Ward asked if any member would speak in its favour. No one did so. It had not been intended to take a vote, but someone suggested it and the meeting decided to do so. There were 91 practitioners present, and everyone voted against entering the National Health Service as it now stands.

LONDON SATURDAY JANUARY 24 1948

THE TRAINING OF SPECIALISTS

THE PLACE OF POSTGRADUATE INSTITUTES*

BY

Sir FRANCIS FRASER, M.D., F.R.C.P.

Director of the British Postgraduate Medical Federation

The experience of the war years suggests that the average level of hospital treatment will be raised, but it is not so clear that the standard of the specialist and expert will also be raised, as a result of the new powers and responsibilities of the Minister of Health. There is danger that the effect will be in the reverse direction through too much dependence on the State and the expectation that the Ministry will regulate matters of which it has no experience and for which it may not be willing to accept direct responsibility. It is for the educational bodies to provide the training of a specialist, and the recognition of a specialist should be determined by the profession itself. For the protection of the public it may be wise to state the minimal requirements for recognition, but the standards required by the profession and the public will, it is to be hoped, have little relation to minimal requirements.

In the past the recognition of a medical man as a specialist has depended on his acceptance by his professional colleagues, and I trust that no action by the State will alter this, either directly or indirectly. In the future, under the National Health Service, there will be many more hospital appointments for specialists than there have been in the past, and whatever may be decided about the method of their selection it should ensure that no applicant is appointed who is not accepted by his professional colleagues to be of the standard they require for the post question. A considerable number of memoranda have been prepared recently by the Royal Colleges and the associations of specialists on the experience and training which they recommend, and these confirm and amplify the valuable report of the Interdepartmental Committee on Medical Schools.

Length of Training

In general they advise that following qualification and registration a period of five years' postgraduate experience is required before recognition as a specialist should be granted and that longer is necessary in the more specialized branches of medicine and surgery. In the past the successful candidates for appointments to the senior staffs of voluntary hospitals have as a rule had a considerably longer period. This is clearly desirable, and the training programmes that have been recommended should be regarded as indicating the necessary essentials only. The plan should not be rigid and should permit of considerable variation to suit differences in intellectual capacity, previous education, and experience.

The years of training can be divided into a first period of one to two years of further junior clinical appointments

*Annual address given at the Institute of Laryngology and Otology, Gray's Inn Road, London, on Oct. 10, 1947.

in general medicine and surgery following registration to practise, and a second period of three years and more devoted to training in the selected specialty. At least a year of postgraduate scientific education and laboratory discipline is also advised, which could be associated with the first period and spent in one of the preclinical sciences or associated with the second period and spent in laboratory investigations or research directly connected with the specialty. The programmes recommended include, as a rule, the passing of an examination for a higher degree or diploma as a test of the candidate's progress, but this alone should never be regarded as indicative of fitness to hold a responsible appointment as a specialist on the staff of a hospital.

General Training

The undergraduate curriculum is designed to give the graduating student the principles of the practice of medicine, and to teach method, as the Planning Committee of the Royal College of Physicians points out; and the State may now require a period of twelve months in junior resident appointments in approved hospitals before registration to practise can be granted. While holding these appointments the graduate will obtain practical experience with responsibility for the management of patients, and learn to carry out the technical procedures for diagnosis and treatment that he will be required to perform in the practice of his profession. For a specialist in any of the clinical branches twelve months of practical experience as a resident house-officer is insufficient to provide the wide knowledge of patients and their ailments upon which can be built a wise understanding of any special group of patients and diseases. Until, therefore, the graduate can obtain further junior hospital appointments that provide general experience he should not be encouraged to concentrate on a special subject. These appointments will be normally at an undergraduate teaching hospital or a hospital approved by a medical school and will be of the senior house-officer type. They will be obtained in competition with other candidates for specialist careers, and in this way selection will be exercised. This selection will be progressive, as the graduate competes at each stage for the diminishing number of further appointments suitable for the more advanced stages in his training and, finally, for a specialist appointment on the staff of a hospital.

Special Training

At the end of the further period of one to two years in resident appointments after registration, when the graduate has obtained a wide and practical experience of sick persons and of the routine methods used in diagnosis

and treatment, he will be ready for education in the basic principles of the specialty as an advanced student. For general physicians and general surgeons this advanced education should be progressive over a period of three years at least and be combined with clinical responsibility. For those intending to practise in one of the special branches of medicine or surgery, training as a general physician or general surgeon should be required first, though the period may be somewhat shortened, and a longer total period will be necessary.

Graded Hospital Appointments

This period of special training has not been well organized in the past but has been regulated largely by individual preferences and initiative, and by local circumstances and opportunities. The customary programmes, however casually they have been devised, show much that is common in their patterns, and it is important that this characteristic should be retained to form the basis of the schemes for improvement which are now possible with increased grants for medical education and the institution of a National Health Service. The basis of training has been the holding of a hospital appointment of the registrar type in the appropriate department of a general hospital or, in the case of some special branches, in a special hospital. In the United States of America this type of appointment is generally known as a residency, and in their teaching hospitals has been planned and developed for the education and training of specialists. Stress is laid on the progressive character of the appointment, so that the holder is given increasing responsibilities as his education proceeds, and in its final stage the appointment might be described as that of a resident assistant physician or surgeon. The comparable appointments in this country, known as resident medical or surgical officer, registrar, chief assistant, tutor, etc., vary greatly in the nature of their responsibilities and opportunities, and the duties have as a rule occupied so fully the time of the holder that there has been little opportunity for study and reflection, and the supervision required to make the period one of advanced education has been seldom provided.

It would be a mistake to lay down any rigid programme of training because of the different careers which specialists ultimately follow. The great majority will be fully occupied in the care and treatment of patients, a few will obtain appointments as teachers in the medical schools in addition to clinical appointments in teaching hospitals, and only a very few will follow careers in experimental work or laboratory research. All should, however, be trained to use their opportunities for clinical observation to advance knowledge, and all should reach such a standard of general education and culture as befits the leaders of a learned profession.

The first stage of the registrarship should if possible be held in a *general teaching hospital* and medical school. There the graduate will be in contact with many others in a similar stage of training, though aiming at specialization in other branches and holding appointments in other departments, and in contact also with experienced practitioners and teachers in his own and in other specialties. The staffs of the pathological and pre-clinical departments will be ready to help and advise, and their laboratories will be open to him. Library facilities and a museum will be available and he will have opportunities for teaching undergraduates and house-officers. Teaching of this kind and discussions with their contemporaries and seniors should be arranged for the registrars, as these are as important in their training and development as responsibility for the care and treatment of patients. A considerable increase in the number of registrar posts in teaching hospitals is proposed, and this should make it possible in most instances for at least the first year of training to be spent in this way, and at the same time enable the holders of these posts to have more time for study, discussion, and reflection than has been usual in the past.

The clinical material at an undergraduate teaching hospital is regulated by the needs of undergraduate education and, except in general medicine and general surgery, there will seldom be enough patients to provide the registrars with the wide practical experience they require in the technical aspects of their specialties. The second stage in their training might well be arranged to provide this by an appointment for a year or longer in a *regional hospital centre* with a large department for the particular specialty, where the training will be more practical and where the registrar will have opportunities for gaining experience the skill in diagnosis and treatment which he will require. The hospital or special department should be approved for the purpose by the regional postgraduate committee, for his training must still be closely supervised.

The third stage should vary according to the progress made during the earlier stages and to any aptitudes which the candidate has displayed. If he is a promising undergraduate teacher he might return to his original or some other teaching hospital, and if he has shown ability for original research he might be appointed to a professorial department. On the other hand, if his inclinations and abilities point to a life devoted to the treatment and management of patients a further period in a non-teaching hospital might be best to equip him for a career as a regional specialist and consultant. At some period in his training, no matter what his eventual career may be, he should be given opportunities to see the practice of his specialty in other centres, either by a hospital appointment, another part of the country or by a period of study abroad. London there are peculiar advantages in an appointment at one of the *special postgraduate hospitals* with the visiting staff representative of the practice and teaching of the general medical schools, for the graduate will be able to obtain there a wider view of the specialty and to form his own opinion on the comparative values of different methods.

Courses of Instruction

In most subjects organized courses of postgraduate instruction are available, consisting of lectures and demonstrations, with varying opportunities for practical work in the wards and out-patient departments. In the training of a specialist these courses cannot take the place of graded hospital appointments with increasing responsibilities. They can, however, play a part. It is doubtful if the best type of graduates who obtain appointments of the registrar type at teaching hospitals and hospitals associated with medical school over a period of three years or more get much from an organized course, but there are graduates who lack the ability to generalize from their experience. For them a well-planned course can be of great value, enabling them to appreciate the principles underlying the practice, to synthesize their knowledge, and to clear their minds of doubts and difficulties. For those who have been unfortunate in their hospital appointments a good course can fill the gaps in their knowledge and compensate to some extent for the deficiencies of their earlier training. Such a course should be of the advanced revision type, needs skilful planning, and for its success requires a group of able instructors who are keen and experienced teachers as well as experts in their specialties. Only a few courses of this type are available at present.

The usual type of organized course is more suitable as an introduction to a specialty and provides a background for further training by means of hospital appointments. Unfortunately they often enable candidates to obtain diplomas and thus to appear qualified to practise a specialty in which they have not been adequately trained. Success in passing the examination for a special diploma is evidence of progress, not of completion of training as a specialist.

Lectures.—Lectures designed to supplement responsible work with patients are available in most of the specialties. Given by experts each on the subject in which he is specialist.

interested, with no attempt to cover the field systematically, they can be of considerable value by indicating the directions in which progress is being made, the gaps in current knowledge, and the literature that should be studied. When the lecturers are drawn from all the medical schools in the country such a series can be of great educative value and a stimulating experience.

Research.—There are a relatively small number of graduates whose intellectual capacity and earlier education enable them to develop as fast as their teachers can take them and whom it is a joy to teach. If given the appropriate opportunities and encouragement during their training they are likely to contribute to the advance of knowledge in the specialty. They should be watched for continually and be attached to individual members of the clinical or laboratory staffs to assist them in their investigations and in experimental research. Hitherto there have been very few departments with staff, accommodation, and equipment of university standard in the clinical subjects, except general medicine, general surgery, and obstetrics, and opportunities for higher education and research in the special clinical branches have been difficult to obtain. This has been a serious drawback to specialist education in this country, and the increased financial grants which the Government is now giving for medical education will, it is hoped, improve the position and provide opportunities for this the highest form of medical education and the essential inspiration in the training of specialists.

Graduates from Overseas

This scheme of progressive training, based on competitive selection for hospital appointments and supplemented by courses of instruction, has been outlined with particular reference to the graduates of our own medical schools, and it is necessary to consider how the graduates from overseas can be welcomed and fitted into it in accordance with their requirements. They visit us at various stages in their postgraduate education; they remain here for a few months or for two or three years; they may aim at obtaining the best training we can provide or they may plan to return to their own countries before reaching the standards that we regard as essential.

There are those who have spent several years in graded hospital appointments in their own country and come here for a few months in order to see something of the practice and listen to the teaching of our eminent specialists. An advanced revision course covering two or three months and attendance at a series of lectures by experts from the different centres fulfil their first needs and help them to make those personal contacts that add so much to the educational value of their visit. The remainder of their time can be used to advantage by attachment to individual teachers whose methods and philosophy can be studied only by close association.

For those who visit us at an early stage in their training a longer course of basic instruction, with clinical work, demonstrations, and lectures, is required in order that they may acquire sound principles and technical skill. They may then return to their own countries to continue their training by further hospital appointments. Some will obtain them here and remain for several years, sharing with our own graduates the system of registrar appointments with progressive responsibilities.

Most of the graduates from overseas come to London for part at least of their time in this country, though many obtain what they require at other centres in the first instance, and the opportunities provided in Edinburgh are a notable contribution. The majority of the graduates who come to London come with the intention of acquiring one or more special diplomas. In the minds of many of those from overseas the acquisition of a diploma is more important than experience in the specialty, and they are content to spend the whole of their time here in reading books and listening to lectures. The special diplomas vary greatly in their standards; some should be regarded as little more than qualifying the successful candidate to enter on a period of proper training; few can be accepted as indicative that the candidate is fit for the responsibilities of a specialist and that his training is completed. Few persons, apart from those directly concerned, appreciate the standards of the different diplomas; and there is much misconception of their

values in the minds of the public and of the non-medical members of hospital boards even in this country, and they are often given entirely false values by official bodies overseas. Most of the special diplomas are awarded by the Royal Colleges, which arrange series of lectures of considerable educative value, for they indicate the standards of learning which a specialist should possess, without attempting to cover the subjects systematically, but they cannot themselves provide the clinical work essential for the training of a specialist. There is, I believe, a real danger that London may come to be regarded as a purveyor of diplomas, a reputation that might interfere seriously with its development as a great centre of postgraduate education. Closer co-operation between the Royal Colleges, the associations of specialists, and the medical schools is clearly desirable to ensure that the special diplomas take their proper place in the education of specialists.

The number of clinical appointments suitable for specialist training at the general teaching hospitals associated with the undergraduate medical schools has hitherto been insufficient for the training of our own graduates, and only rarely has it been possible for them to provide posts for visitors from overseas. The staffs of the undergraduate teaching hospitals have been fully occupied with the education of undergraduates and they have been unable to contribute to any great extent to the training of the large and increasing numbers of visitors. The experience of the post-war years and the need for additional or supernumerary appointments to provide for medical officers released from the fighting Services have shown that in general medicine and general surgery opportunities eminently suitable for the training of specialists can be provided at the general teaching hospitals to a considerably greater extent than has been the practice in the past. If a few appointments of this type could be allotted at each of the teaching hospitals to selected graduates from overseas it would make a most welcome contribution to the training of specialists for the Commonwealth and Empire. In the special branches of medicine and surgery, however, the undergraduate medical schools, maintaining a proper balance between their general and special departments, cannot as a rule be expected to develop departments with the staff, accommodation, and equipment required for advanced education and research. Appreciating the increasing demand for postgraduate education in London and the peculiar opportunities for creating university departments in the special branches in association with London's famous special hospitals, the University of London has embarked on a policy of developing postgraduate institutes for higher education in the major clinical specialties.

The Postgraduate Institutes

The institutes are being developed from the postgraduate teaching that has been carried on for many years at certain of the special hospitals of London. In addition to resident hospital appointments and the very important training which they provide, the instruction has varied considerably in standard, and has consisted for the most part of clinical demonstrations and lectures, planned in some instances to suit the requirements of candidates for diplomas. In only a few instances was it possible to provide the advanced education that should be regarded as essential for a specialist and consultant, and it is, I think, significant that the standard of education has been generally higher in those special branches in which there are no diplomas.

The aim of the University of London, and of the British Postgraduate Medical Federation acting on behalf of the University, is to provide opportunities for research and higher education in each of the major clinical specialties, with staffs appointed to advance knowledge not only in the clinical field but also in the sciences upon which the practice of each is based. Each institute should be the centre in London of thought and practice to which the specialists will look for help and above all for inspiration. The staff of each institute should be representative of the special departments of the undergraduate medical schools and the general teaching hospitals, and the University will

look to the institute for advice on academic matters concerning the specialty.

As soon as practicable the University will be asked to appoint professors or readers at each of the institutes. Their assistants should be the best of the younger men available from all sources for advancing their subjects by research and experiment, and it should be possible to offer accommodation at each of them to specialists established elsewhere, either at home or abroad, to enable them to work on approved problems. Clearly it will take some time to provide at each institute the laboratory accommodation and equipment, the libraries and museums, that are required, but until this is done the institutes cannot fulfil their main purpose; for teaching must always be dull, uninspired, and lacking in the essential element of excitement unless there is an atmosphere of investigation and progress. This is especially necessary in advanced or postgraduate education.

The number of appointments of the house-officer and registrar types at the teaching hospitals associated with the institutes should be regulated by the recognition that these are training appointments and that leisure for study and reflection is required. In most of the postgraduate teaching hospitals they could be increased in number. These appointments represent the principal method of practical training in the specialty and should be graded to provide progressively increasing responsibilities. The postgraduate teaching hospitals have a peculiar responsibility for graduates from overseas, and they will, I hope, agree to reserve some proportion of their appointments for candidates sponsored by the universities of the Dominions and selected by the representative committees being formed for this purpose.

As a result of interviewing large numbers of graduates coming to London from other universities in this country and of graduates from overseas seeking specialist training here, I believe that to meet their requirements there should be two types of courses of instruction in each specialty. One type should be designed to serve as an introduction to the specialty, to provide training in its basic principles and technical skills, and to give a sound educational basis to the subsequent periods of training by hospital appointments, either here or on the return of the graduate to his own country. With practical work in wards, out-patient departments, and laboratories, supplemented by group discussions, lectures, and demonstrations, such a course can, if organized to cover a period of six months or so, contribute materially. It cannot replace responsible appointments, and the object of the course should be preparatory and educative rather than vocational. In connexion with the course each institute will arrange a series of lectures on the applications of anatomy, physiology, biochemistry, pharmacology, and pathology to its special subject; but there is much, I would suggest, in the application of these sciences that is common to all the special branches of medicine and surgery, and it should be possible to arrange also a central series of lectures in the basic sciences which candidates in all the specialties might attend. The lecturers would be drawn from the medical centres throughout the country, and the series might be organized with the co-operation of the Royal Colleges. There is a philosophy inherent in every specialty which it is the duty of the institutes to foster and impart, and the history of the specialty, its contributions to medicine, to culture, and to the life of the community should be stressed.

The other type of course should be designed to co-ordinate and systematize the practical experiences of the graduate who has completed his training and his hospital

appointments either in this country or abroad, to indicate the frontiers of knowledge and lines of progress, and to renew his enthusiasm. Advanced revision courses of this kind are peculiarly exacting on the teaching staff. They should be based on the examination, investigation, and demonstration of selected cases by the graduate students themselves, followed by group discussions of the subject and its literature. Only those graduates who are sufficiently advanced in their training to make good use of these opportunities should be accepted, and the class should be strictly limited in size and divided into small groups for much of the work. Such courses need not extend over more than eight to ten weeks, and they would be most suitable also for established specialists from the regional hospitals of the National Health Service or from overseas who will return to London from time to time for the continuation of their education. They would preferably be part-time, to allow of attendance at other hospitals and institutions and for the study of more general subjects, and a series of lectures on the clinical aspects of the specialty by its eminent practitioners drawn from all the centres in this country might be arranged, with the co-operation of the Royal College especially concerned, to take place at the same time.

Present-day Difficulties

This programme of research, clinical experience, basic training, and advanced revision cannot be fully carried out until considerable increases in accommodation are provided and until suitable staffs can be appointed. Much can be done and is being done now with improvised accommodation and the eager co-operation of existing staffs and hospital authorities. Further progress depends largely on finding suitable persons to direct research and organize the teaching who are able to devote their time to these duties, as well as on the new Boards of Governors of the teaching hospitals that are to be appointed by the Ministry of Health.

During the immediate post-war years there has been a heavy demand for postgraduate education, and the plan for a National Health Service in this country and of similar services in the Dominions and elsewhere have created an unprecedented pressure on our provisions for specialist training. The postgraduate teaching hospitals and medical schools throughout the country have met this pressure by increasing the numbers of students accepted for courses and of appointments of the registrar type, and this has put a heavy burden on their teaching staffs. With the establishment of the National Health Service and the appointment of postgraduate committees in each of the regions it is hoped to extend the opportunities for specialist training and to use the hospital centres in the regions for postgraduate education. This will enable the institutes of the University to be more selective in their acceptance of applicants. For many visitors from overseas instruction of a practical type would be more appropriate than the advanced education which the institutes will provide, and there are some whose training in general medicine and general surgery has not been sufficient for them to make use of the opportunities which the institutes will offer. Others come to London to attend a course in one or more of the specialties in order to add to their equipment for general practice. It should become possible, in due course, suitably to place postgraduates of all types and leave the institutes free to develop as departments of the University and to become focal points of postgraduate education in their specialties. They should be institutions for higher education and research, but they should also be responsible for the co-ordination of training in their subjects in the London area.

Much has been accomplished, and the start is a promising one.* At other universities plans are being developed which will contribute to the same end. Differing in detail and shaped by local conditions, they will provide a welcome stimulus through rivalry. There is still a long way to go before the aim of the University of London is realized and before the peculiar opportunities present here in London are developed fully. When that time comes the postgraduate institutes will send out the future leaders of medical thought and practice, and will be able to welcome those who seek to advance knowledge by research and to improve their skill for the relief of suffering.

SMALLPOX IN STAFFORDSHIRE, 1947

OUTBREAK AT BILSTON

BY

C. SIMPSON SMITH, M.B., B.S.

Assistant Medical Officer, Staffordshire County Council

The following report covers the outbreak of smallpox which occurred in the borough of Bilston and in the neighbouring areas of Coseley U.D.C., Willenhall U.D.C., and Dudley C.B., as it is assumed that all the cases were from the same source. Thirty cases were confirmed by the Ministry of Health and seven others were removed to hospital as suspects. One associated case occurred in the Birmingham area—a medical student who had visited the smallpox hospital; this is not included in the present series. Six cases were fatal—five haemorrhagic and one confluent smallpox.

History of the Outbreak

An Army sergeant aged 23 was granted compassionate leave from India. He left Agra by train on Feb. 17, 1947, boarded a plane at Karachi on the 20th and, flying via Basra, Cairo, Malta, and Marseilles, arrived at Heathrow Airport on the 23rd. Next day he travelled to his home in Bilston. He had been vaccinated in infancy and again on Nov. 3, 1944, and Feb. 15, 1946.

On March 1 he felt slightly ill, but remained ambulant until he developed a rash on March 6, when he said he felt as if he had "flu." The local medical officer of health, Dr. B. C. Haller, did not feel happy about the case and attempted to obtain the opening of the smallpox hospital. However, further opinion was sought through the regional office of the Ministry of Health, and a confident diagnosis of chicken-pox was made on March 8.

The patient remained at home, and his mother developed a rash on March 21. A diagnosis of chicken-pox was again made. An unvaccinated man of 21 years, who had visited the soldier on March 6, developed a more severe rash on March 25. Further consultations took place and specimens were sent from the two later cases for laboratory investigation. A preliminary report on April 1 suggested that the condition was variolous. Further experts were called in and a conference took place on April 3, at which time "reliable clinical opinion still regarded the Bilston cases as chicken-pox" (Regional Ministry Circular).

On the 4th the mother and brother of Case 3 were taken ill and developed rashes on the 8th. By this time confirmatory reports on the laboratory investigations left no doubt that Cases 2 and 3 were smallpox, and the hospital was opened on the 9th, the first two cases having by this time recovered. The outbreak was regarded as variola minor (*Med. Off.*, 1947, 77, 152), but subsequent events proved the infection to be of the major variety.

*In addition to the Postgraduate Medical School of London, institutes have been established, or are in process of development, in child health, neurology, laryngology and otology, ophthalmology, psychiatry, diseases of the chest, cardiology, dermatology, orthopaedics, urology, and dental surgery.

From Case 1 three further cases originated: the grandmother developed haemorrhagic smallpox and died before removal, and the father and sister developed modified eruptions. No further cases were reported from the known source, but ample opportunity for spread of the infection had been afforded in the 34 days which elapsed between the appearance of the rash in the soldier and the opening of the hospital. One case was known to have travelled from Bilston to Coseley by bus in the late prodromal stage.

Subsequent groups of cases developed in which no apparent origin could be traced, despite vigorous detective work on the part of the staff. The last case was admitted to hospital on July 9 with a confluent rash after being ill at home for six days; an initial diagnosis of measles had been made. This patient lived some four miles from the original focus and her source of infection remains unknown. She had numerous visitors during her period at home, but no contact cases were reported. The 30 cases are classified in Table I and their histories given in Table II.

TABLE I.—Summary of Confirmed Cases

	Severe Cases (15)	Mild Cases (15)	
Haemorrhagic	5 (all fatal)	Copious discrete	1
Confluent	8 (1 fatal)	Moderate discrete	1
Semi-confluent	2 (none fatal)	Mild discrete	6
		"A few spots"	7

Commentary

Cases were seen before admission by experts of the Ministry's Regional Panel, and where doubt existed further examinations were made after admission.

In the *Monthly Bulletin of the Ministry of Health and Public Health Laboratory Service*, July, 1947, special attention was drawn to the fact that the three contacts of Case 9 who developed the disease had been unsuccessfully vaccinated on May 17, 1947, and revaccinated on May 23. This was later found to be incorrect. When examined on the 23rd the reaction to the incisions performed on the 17th was very indefinite and further incisions were made. By the 25th, however, the vaccination of the 17th showed a good reaction.

Group 7 (Bilston).—Opinion was sought in regard to Case 22, aged 7, who was gravely ill. As the other children in the household presented minor lesions they were admitted to hospital. Cases 21 and 23 were regarded by the Ministry expert as confirmed smallpox, but an infant aged 10 months and an older sister, both vaccinated, were not confirmed. When Case 21 was seen in hospital on June 30 a scar was noted on his ankle, and it was suggested that he might have been the original source in the household. No other lesions were then present. Local opinion considered that the scar was due to an old infection caused by a protruding nail. Further opinion on July 7 doubted if the case ever was smallpox. Case 23 was very fretful and obviously ill on removal, but the rash failed to develop beyond the macular stage. She was vaccinated after admission to hospital.

Case 24.—This boy had papules on the forehead only, which soon scabbed and left depressed scars showing staining. The laboratory results were negative, but his was regarded as a highly modified case when seen on July 7. His sister was removed to hospital as a suspected case, but her condition soon subsided and she was regarded as suffering from a vaccinial lichen. It is possible that the boy also was suffering from an eruption of this type.

Case 30 (Dudley).—Clinically this was the most interesting case of the whole outbreak. The prodromal phase was marked with headache, chill, malaise, and backache. The rash appeared on June 19 and streptococcal septicaemia was diagnosed. The patient was removed to the infectious diseases hospital on June 21 by ambulance and before being sent to the ward he was seen by a medical officer who had seen Case 9. As Case 30 presented a similar picture he was transferred to the smallpox hospital. He had a marked

TABLE II.—Case Histories

Case No.	Sex	Age	Source of Infection	Vaccinal State	Final Diagnosis	General Remarks
BILSTON CASES						
<i>Group 1 (8 cases)</i>						
1	M	23	India	Infancy 3/11/44	Mild discrete	Prodromal phase 1-6/3/47, "like 'flu.'" Rash on palate, face, back, shoulders, and chest. Quick maturation and slight depth
2	F	50	Son (Case 1)	15/2/46 Infancy	"	Febrile 19-21/3/47. Rash on 21/3/47: palate, face, trunk, forearms, legs. Well-marked vesicular stage. Laboratory confirmation
3	M	21	Case 1	Unvaccinated	Semi-confluent	23/3/47, severe malaise; 25/3/47, rash profuse on face, forearms, palms, legs, and soles. Laboratory confirmation
4	F	48	Son (Case 3)	Infancy 3/4/47	Confluent	Onset 4/4/47: marked rigors. Rash 8/4/47: profuse, typical distribution. Penicillin given from 14/4/47. Laboratory confirmation
5	M	17	Brother (Case 3)	3/4/47	"	Onset 4/4/47: prodromal phase marked. Rash 8/4/47. Penicillin given from 14/4/47
6	M	51	Son or wife (Case 1 or 2)	1914-18 10/4/47	Mild discrete	Onset 8/4/47: malaise. Rash 11/4/47. 20 lesions: forehead, arms, scapulae. Laboratory confirmation
7	F	19	Brother or mother (Case 1 or 2)	Infancy 10/4/47	"A few spots"	Onset 8/4/47: slight malaise. Rash 11/4/47. 9 lesions in all. Laboratory confirmation
8	F	79	Grandson (Case 1)	? Infancy	Haemorrhagic	Onset 8/4/47: gravely ill. Petechial rash 10/4/47. Died 11/4/47
<i>Group 2 (4 cases)</i>						
9	M	70	Unknown	Unknown ? Infancy	Haemorrhagic	Onset 26/4/47: headaches. 29/4/47: rash; petechial on trunk and extremities. Bruising on arms, hands, and feet. Blood p.r. Penicillin given. Died 2/5/47. Laboratory confirmation
10	F	64	Husband (Case 9)	2/5/47 (primary reaction)	Confluent	Onset 7/5/47: prodromal phase slight. Rash on 11/5/47. Penicillin given from admission on 11/5/47
11	M	30	Case 9	3/5/47 (primary reaction)	"	Onset 7/5/47: severe pain in abdomen. Rash on 11/5/47. Penicillin given
12	F	41	Case 9	2/5/47 (primary reaction)	"A few spots"	Onset 11/5/47: symptoms slight. Rash on 13/5/47: 7 pustules in all. Positive laboratory culture
<i>Group 3 (4 cases)</i>						
13	F	27	Unknown	Unvaccinated	Haemorrhagic	Onset 9/5/47: severe sickness, headache. Rash on 12/5/47; diagnosed as scarlet fever. Admitted 16/5/47. Petechial rash: confluent on face, neck, and throat; discrete on back, abdomen, and limbs. Palms and soles clear. Blood from all orifices. Died 16/5/47
14	F	49	Daughter (Case 13)	Infancy 17/5/47 23/5/47	"	Onset 29/5/47: intractable headache, abdominal pain. Rash first appeared 31/5/47. Confluent petechial rash by 2/6/47. No maturation. Died 5/6/47
15	F	14	Sister (Case 13)	Infancy 17/5/47 23/5/47	Mild discrete	Onset 30/5/47: no symptoms, but acneiform rash which was vesicular on 31/5/47
16	F	12	Sister (Case 13)	Infancy 17/5/47 23/5/47	"	No prodromal stage. Rash on 1/6/47. Vesicular. Ambulant throughout.
<i>Group 4 (1 case)</i>						
17	F	11	Unknown	Unvaccinated	Confluent	Onset 16/5/47: abdominal pain. Rash 19/5/47. Treated with penicillin from 19/5/47
<i>Group 5 (1 case)</i>						
18	F	39	Unknown	Infancy 4/6/47 (successful)	Moderate discrete	Onset 1/6/47: rigors, etc. Rash 4/6/47; maculo-papular, mainly on legs and arms. None on face. Treated with penicillin
<i>Group 6 (2 cases)</i>						
19	M	61	Unknown	Infancy	Copious discrete	Onset 9/6/47: backache. Atypical rash on 13/6/47; papular on forehead and scalp, acneiform on body. Specimens reported "presumptive negative." Quick maturation and removal on 17/6/47. Later material positive. Treated with penicillin
20	F	61	Husband (Case 19)	Infancy 16/6/47	"A few spots"	Vague onset 26/6/47. Rash appeared 28/6/47. Scattered papules on body and extremities. None on face. Laboratory confirmation
<i>Group 7 (3 cases)</i>						
21	M	11	Unknown	May, 1947	"A few spots"	Removed to hospital with Case 22. A few indeterminate lesions. Laboratory negative
22	M	7	Unknown. ? Case 21 (brother)	Unvaccinated	Confluent	Onset 18/6/47: pains in back, severe diarrhoea. Rash 20/6/47; confluent. Treated with penicillin. Died 2/7/47
23	F	2	? Case 21 (brother)	"	"A few spots"	Onset 20/6/47. Removed same day with macular rash which did not mature. Laboratory-negative
<i>Group 8 (1 case)</i>						
24	M	10	Unknown	23/6/47	"A few spots"	Onset 30/6/47: little discomfort. Rash on 3/7/47, forehead only. Laboratory negative

<i>Group 1 (2 cases)</i>						
25	F	78	Unknown	Infancy	Haemorrhagic	Source probably indirectly from original Bilston case. Onset obscure (patient an invalid). Rash on 7/5/47; petechial. Died 15/5/47
26	M	72	Sister (Case 25)	10/5/47	"A few spots"	Onset 22/5/47: slight symptoms. Two lesions on wrist on same day, positive for variola. No other lesions
<i>Group 2 (2 cases)</i>						
27	F	18	Possibly Group 2 (Bilston)	6/5/47	Confluent	Onset 13/5/47: prodromata fairly severe. Rash 16/5/47; initial diagnosis "measles." Admitted 19/5/47. Penicillin given
28	F	52	Daughter (Case 27)	20/5/47	Semi-confluent	Onset 27/5/47: headache. Rash 29/5/47, papular on admission on face, neck, trunk, limbs, and in the axillae
WILLENHALL AREA (1 case)						
29	F	19	Unknown	Unvaccinated	Confluent	Onset 3/7/47: dysphagia. Rash developed 6/7/47: original diagnosis "measles." Removed 9/7/47. Gravely ill. Penicillin given
DUDLEY AREA (1 case)						
30	M	45	Unknown	Infancy 25/6/47	Mild discrete	Onset 16/6/47. Original rash 19/6/47. Later crop 1/7/47

vesicular rash on the forehead, face, neck, and thorax; pronounced excretion of the skin in the neck area; a papular rash on the arms and legs but none on the palms and soles; a haemorrhagic rash on the lower thorax and abdomen; and some lesions in the mouth. He complained of severe abdominal pain. His was suspected to be a haemorrhagic case, and penicillin was administered. The rash continued to extend and the haemorrhagic areas became brighter until June 24, when the rash faded quickly, although the tempera-

ture remained raised and the abdominal pain persisted. Laboratory findings at this stage were negative. By June 30 the rash had completely faded, and a Ministry expert expressed the opinion that it might have been erythema multiforme. There were never any bullae, severe stomatitis, or pseudomembrane in the mouth. On July 1 a new crop of lesions appeared, beginning as a vesicle on the abdomen within a previously haemorrhagic area. Specimens gave a positive culture for variola. By July 4

there were more papules present on the hands and chest, the temperature became normal, albumin disappeared from the urine, and the patient felt better. On July 7 an expert confirmed the rash as being a modified smallpox of some six days' duration. Further progress was uneventful. While for record purposes this case was classified as mild discrete smallpox the possibility remains that it was a haemorrhagic case, with a prolonged prodromal period and slow maturation, which recovered.

Suspected Cases

The following four suspected cases were removed to hospital but were not confirmed as smallpox.

An unvaccinated child of 7 years had severe vomiting and epistaxis. Next day a provisional diagnosis of " ? varicella, ? variola " was made and she was admitted to a special isolation unit. On admission she was delirious, with a profuse macular rash on the face, trunk, and palms of the hands. By the following day she had developed post-occipital glands and the rash was fading. Subsequent progress proved the condition to be rubella.

A woman aged 27 developed a profuse papular rash on the hands, shotty to the touch, with a few vesicles, 16 day after vaccination. Laboratory evidence was negative and the lesions soon cleared, leaving considerable brown staining. This was probably a vaccinal eruption. There was no previous history of urticaria.

A girl aged 22 who had been vaccinated in infancy and again on May 17, 1947, developed a rash on June 14 after a well-marked period of sickness, abdominal pain, back-ache, and conjunctivitis. She had three papules on the forehead, one on the chin, and one on the right leg which became vesicular. Opinion was divided, but she was removed to hospital, where laboratory evidence was negative. The scarring from the lesions was depressed and showed staining.

A man aged 31 who worked in Bilston was vaccinated on May 21, 1947, and developed a rash on June 17 with no initial prodromata. He was removed to hospital with a generalized rash, which gave negative laboratory evidence.

It is suggested that the last two cases may possibly have been late effects of the vaccination.

General Measures Taken in Bilston

Contacts.—All possible steps were taken to obtain lists of contacts, who were kept under surveillance for a period of 21 days to cover any possibility of a prolonged incubation period in vaccinated or modified cases. In the later stages of the outbreak considerable help was given by the Army authorities, a field hygiene unit being drafted in to help in the daily visitations, which then numbered several hundreds.

Vaccination.—Vaccination was offered to all known contacts, and a special clinic was opened to facilitate the work of the public vaccinators. All contacts received three incisions. No endeavour was made to advocate mass vaccination, as it was felt that the protection of the known contacts was the important factor. However, by the middle of May the public panicked at the continued incidence of cases, and the demand for vaccination became so great that assistant medical officers of Staffordshire County Council had to be called upon to act as deputies for the public vaccinators. It is estimated that over half the population of Bilston were vaccinated at the clinics and works or by the practitioners. No cases of encephalitis following vaccination were reported in the Bilston, Coseley, and Willenhall areas.

Chicken-pox.—Section 147 (1) Public Health Act, 1936, was brought into operation and chicken-pox was notifiable from May 19. All cases were visited by the medical officer of health, and several adult cases remained suspect until proved negative.

Staff.—All staff in any way connected with the cases were revaccinated at six-weekly intervals, as it was felt that a virus of very high virulence was responsible for the outbreak.

Hospital Arrangements.—A small disused infectious diseases hospital was opened by the Smallpox Board and staffed by volunteers. Although the hospital was situated in Bilston the distribution of the cases gave no evidence of aerial spread.

Treatment of Patients

General.—Patients were nursed until the crusting stage in darkened rooms. The eyes were treated with boric lotion and sulphacetamide drops. Frequent mouth-washes were given. Lesions occurring on the face and neck were treated with hot sodium bicarbonate compresses, as they were found to be very soothing.

Sedatives.—"Nembutal," $1\frac{1}{2}$ – $4\frac{1}{2}$ gr. (0.1–0.3 g.), was administered according to the age and condition of the patient.

Use of Penicillin.—As already indicated, penicillin was administered to most of the severer cases. In the first two to receive it it was started in the pustular stage, 20,000 units being given intramuscularly at three-hourly intervals, then being changed to 100,000 units six-hourly. It was later suggested that a dose given twice daily would maintain an effective concentration and cause less disturbance to the patients. Later cases received 1,000,000 units twice daily from admission to the crusting stage. The dosage was purely empirical. This is a greater dose than has previously been noted in the treatment of smallpox (Easton, 1945; Foulis, 1945; Pierce, 1947). One cannot claim too much from the small series, and it is not suggested that penicillin influenced the course of the virus infection. In the pustular stage there was much less photophobia and pus formation, and the nursing staff noted agreeably the great diminution in the quantity of soiled linen. Cultures taken during the pustular stage grew only penicillin-resistant *Staphylococcus aureus*.

The mortality rate compares favourably with other recent epidemics, only one confluent case being fatal—that of a previously debilitated child.

TABLE III.—Comparison with Other Recent Outbreaks of Smallpox

Outbreak	Total Cases	Deaths	Haem. and Haem. Confl.	Confluent	Semi-Confl.	Mild	Severe Cases*	
							%	Mort. %
Glasgow, 1942	36	8 (22-2%)	3 (3)	9 (5)	2	22	38.8	57
Edinburgh, 1942	36	8 (22-2%)	6 (6)	5 (2)	3	22	38.8	57
Middlesex, 1944	11	3 (27-3%)	1 (1)	2 (2)	8	27.3	40.9	50
Middle East, 1944	48	13 (27-5%)	11 (10)	5 (3)	10	22	54.1	75
Merseyside, 1946	31	9 (29-0%)	8 (5)	7 (4)	2	19	38.7	50
Bilston, 1947	30	6 (20-0%)	5 (5)	8 (1)	2	15	50	40

* Severe cases comprise the haemorrhagic, confluent, and semi-confluent. The bold figures in parentheses indicate the number of fatal cases.

Lessons of the Outbreak

Once again an outbreak of smallpox followed a confident diagnosis of chicken-pox by competent experts. This also occurred in 1947 at Scunthorpe (*Medical Officer*, 77, 152), in the Middlesex outbreak of 1944 (Bradley, Davies, and Durante, 1946); the Edinburgh outbreak of 1942 (*B.M.J.*, 1944, 2, 54); and at Birkenhead in 1946 (Pierce, 1947). Had the original case at Bilston been removed to complete isolation it is probable that the outbreak would have terminated in the original group. One can but echo C. K. McKillop (1947): "Chicken-pox in adults should always be regarded with suspicion."

The possibility of a modified attack of variola should always be borne in mind when suspicious rashes occur in vaccinated persons who have recently arrived in this country by air. The impact of such a case on a comparatively unvaccinated population was well demonstrated in the Bilston outbreak. One would have expected further cases to arise, especially in the overcrowded conditions prevailing in the area, and the early removal of the patients, with vaccination and close surveillance of the contacts, must have been contributory factors in limiting the spread. Mild missed cases in vaccinated persons must account for the missing links in the spread of the outbreak, the termination of which can be described only as natural or spontaneous.

Laboratory investigations have been of great help in confirming some cases, especially in the original group and in highly modified attacks such as Case 26. However, time must elapse before the receipt of the reports and of negative results in cases showing definite clinical signs.

As in previous outbreaks, vaccination did not fully protect within the first week of the vaccination period. Many contacts were vaccinated too late in the incubation period, owing to delay in diagnosis or even in sufficient suspicion of the true nature of the case. Confluent cases occurred where successful vaccination had been carried out nine and eight days before the appearance of the true smallpox rash, and in one haemorrhagic case successful revaccination had been carried out 12 days before, yet the case had a fatal termination. Modified cases occurred where vaccination had been carried out 12 days before the rash appeared. Many individuals vaccinated in the Services during the recent war years gave reactions which indicated absence of immunity.

An important administrative point in dealing with vaccination of school-children is the necessity for obtaining the written consent of the parents. In the rush of children coming for vaccination from the schools it was assumed that parental consent had been given. Later it was found that some children had been vaccinated "to be in the fashion," without parental consent.

Summary

An outbreak of smallpox is described originating in a soldier who travelled from India by air and was at home for some days before he developed a modified attack of variola which was regarded as chicken-pox.

Of the 30 confirmed cases, 15 were severe, with 6 deaths—5 from haemorrhagic smallpox and 1 in an unvaccinated confluent case.

I wish to express my appreciation of the very great help given to me by Dr. B. C. Haller, medical officer of health for Bilston, during my period of special duty in the area and for his permission to utilize the various records and reports. My thanks are due to his staff for their ready co-operation at all times. I am greatly indebted to Dr. F. Asker, medical officer of the Joint Infectious Diseases Board, and to Miss Marian Curtin, the matron of the Moxley Hospital and Bilston Smallpox Hospital, for their help in giving me access to the cases and treatment records and for permission to use the records in collating this report. I also wish to record my thanks to Dr. G. Ramage, medical officer of health for Staffordshire, for his permission to publish this report.

ABSORPTION OF VITAMIN D IN STEATORRHOEA

BY

L. P. R. FOURMAN, M.D.

AND

G. H. SPRAY, D.Phil.

(From the Nuffield Department of Clinical Medicine,
University of Oxford)

Osteomalacia, though rare in this country, may sometimes be seen as a complication of steatorrhea. Ryle (1924) and others have suggested that the formation of insoluble calcium soaps in the fatty intestinal contents inhibits calcium absorption in this condition. Although unabsorbed fat in the bowel does affect calcium absorption (Telfer 1926-7), soap formation cannot entirely explain the failure to absorb calcium, otherwise the patients should absorb calcium normally on a fat-free diet. In fact, restriction of fat intake alone does not improve calcium absorption (Bauer and Marble, 1932; Bassett *et al.*, 1939), but vitamin D rapidly restores it to normal even with a normal fat intake, indicating that the patients are vitamin-D-deficient. It was suggested that this was due to a failure of absorption of the vitamin, but no direct evidence of such an effect has been given. In three cases successfully treated with vitamin D, Bassett *et al.* (1939) used large doses (225,000-900,000 i.u. daily) by mouth, these doses being similar to those required in cases of vitamin-D-resistant rickets (McCance, 1947); they obtained equivocal results when smaller doses (10,000 i.u. daily) were given parenterally to another patient. Bauer and Marble (1932) obtained an immediate response with 10 mg. of ergosterol daily by mouth.

When a woman with osteomalacia due to steatorrhea recently came under our observation the absorption of vitamin D was investigated by comparing the responses to oral and parenteral administration, using doses known to be adequate for treatment of osteomalacia of dietary origin (Liu *et al.*, 1935).

Case History

The patient, a nun aged 61, had worked in Poona from 1933 to 1937. In 1938 a right hemicolectomy, including resection of the last 4 in. (10 cm.) of the ileum, was performed for carcinoma of the caecum; healed tuberculous mesenteric glands were found at operation. After this operation she had diarrhoea, and in July, 1944, she was admitted to this unit for anaemia. Steatorrhea with megaloblastic anaemia was then found. A sternal puncture showed the sternum to be soft; plasma phosphatase was 14 King-Armstrong units but serum calcium and phosphate were not estimated and osteomalacia was not suspected at that time.

Treatment was begun with a low-fat diet with extra meat weekly liver injections, and added vitamins A and D (1,500 units daily), and this regime was continued after discharge. The anaemia and diarrhoea responded fairly well, but in the spring of 1946 she had severe pains in the spine, round the trunk, and in the sacro-iliac joints. Radiographs revealed generalized osteoporosis, and calcium sodium lactate (6 g. daily) was prescribed. This helped to control the diarrhoea, but produced little change in the bone pains. These were rather better after a summer holiday, but this improvement may be ascribed to sunlight rather than to the treatment, for in the spring of 1947 her condition had again become much worse. Every movement of the trunk was very painful; from the lying position she could not sit up without pulling herself up by her arms; her muscles felt weak and she was getting involuntary spasms of the abdominal muscles. Her ribs were very tender. Chvostek's sign was positive, Trousseau's sign

negative. She was admitted to hospital, where the presence of steatorrhea was confirmed, although the anaemia had improved (Hb, 11.7 g. %; R.B.C., 4,400,000 per c.mm.; M.C.V., 91 cu. μ).

The report of biochemical investigations was as follows: blood urea, 35 mg. per 100 ml.; plasma chloride, 464 mg. per 100 ml. (79.5 m.eq./l.); blood bicarbonate, 50 vols. per 100 ml. (22.2 m.eq./l.); blood phosphate, 2.77 mg. per 100 ml. (1.62 m.eq./l.); serum calcium, 8.8 mg. per 100 ml. (4.4 m.eq./l.); plasma phosphatase, 58 King-Armstrong units; plasma proteins, total 4.7 g. per 100 ml.; albumin, 2.75 g. per 100 ml.

Radiographs of the bones revealed considerable decalcification and multiple fractures of the ribs on the right side. These defects, together with the low blood calcium and phosphate and the high phosphatase, confirmed a diagnosis of osteomalacia. The condition had progressed despite the low-fat diet with added vitamin D for nearly three years, and had not responded to the extra calcium intake. During a preliminary period of

mouth was continued, but for the next four periods the same dose was given parenterally. Finally, to determine the effect of the added calcium on fat absorption, fat excretion was measured during a further two four-day periods without any added calcium; calcium balances were not determined for these last two periods.

Calcium intakes were calculated partly from food tables (McCance and Widdowson, 1946), but the calcium contents of calcium lactate and milk were measured direct. These sources accounted for about 4.5 g. of the total daily intake of about 4.6 g., so that the probable error of 10% due to using food tables represented a negligible error in estimating the total calcium intake. With the exception of milk, no foods rich in calcium or which contained much oxalate were given. The bread intake was kept constant. All fat intakes were determined from food tables.

For the four-day collection periods carmine (0.6 g.) was used as a faecal marker, and a rectal washout of distilled water was given to complete each collection. Calcium was determined by titration—in the faeces by the method of McCrudden (1911–12), in the urine by that of Sbohl and Pedley (1922)—while the inorganic phosphate of urine was estimated colorimetrically, using the method of Berenblum and Chain (1938). Faecal fat was estimated gravimetrically after extracting with petroleum ether an aliquot of wet faeces previously treated with hydrochloric acid and dried with plaster-of-Paris.

Results

During the time of the balance observations there was no significant rise in blood calcium or phosphate (see Fig.), despite apparently effective treatment (cf. Bauer and Marble, 1932; Liu *et al.*, 1935). In periods 1–4, with oral vitamin D, 1.9 g. of calcium was retained, while in periods 5–8, with parenteral therapy, 6 g. was retained (see Table). Marked calcium retention began only during the second four-day period after the

Table showing Four-day Calcium and Fat Balances with Oral and Parenteral Vitamin D Therapy

Chart showing the blood findings during treatment with vitamin D.

observation the calcium sodium lactate was increased to 16 g. daily, and the vitamin D to 12,000 units daily by mouth. A low-fat diet (30 g. of fat daily) and liver injections were continued as before. Her pains slowly disappeared, but she remained too weak to get up. Blood findings were practically unchanged (see Fig.). This treatment was continued for five weeks prior to the observations on calcium absorption.

Experimental Observations

The object of the calcium balance observations was to obtain evidence on the absorption of vitamin D. The experiment was begun with a relatively high fat intake (70 g. daily), but time did not permit us to continue the observations on a lower intake. Preliminary tests had shown that 40–50% of the dietary fat was excreted, so that during the experiment 25 g. of calcium lactate was given daily, the diet thus containing more calcium than would combine with this amount of fat in the stools. Observations were made over ten four-day periods, beginning three days after the start of the experimental regime. The fat intake was almost constant throughout the experiment, and the total fat excretion in each period was measured. During the first four four-day periods vitamin D (12,000 units daily) by

start of parenteral therapy. Bauer and Marble found an immediate response to treatment, but Liu *et al.* (1935) and Linder and Harris (1930) also found a negative calcium balance immediately after beginning treatment. The latter authors attributed this to the parathyroid-like action of vitamin D, but the absence of an associated rise in urinary phosphate excretion makes this explanation unlikely (Albright *et al.*, 1946).

The greatly improved calcium balance after parenteral therapy cannot be due to collection errors, for these would affect the results for fat excretion similarly. In fact, fat excretion rose during the second experimental period, when fat absorption was apparently less than 10%. The excessive loss of fat in the faeces was partly due to the high calcium intake: thus the mean daily fatty acid loss in periods 7 and 8 was 71 g., in periods 9 and 10, when no supplementary calcium was given, 34 g.—a difference of 37 g. This amount of fat, assuming an average molecular weight of 271 for fatty acids, would combine with 2.78 g. of calcium. The actual supplementary calcium intake was 3.15 g. This effect of calcium in preventing fat absorption was much more pronounced than in normal people (Fourman), and similar findings in steatorrhea have been

reported by Bassett *et al.* (1939). On the other hand, the results show that once vitamin D was made available the excess of fat in the faeces did not prevent calcium absorption by soap formation. There may be two reasons for this: first, soap formation possibly does not occur until the calcium and fatty acids come together in the colon (Ingelfinger, 1943); secondly, calcium soaps can be utilized, though poorly (Boyd *et al.*, 1932).

Progress Note.—Ten weeks after the conclusion of the experiment blood calcium and phosphate values had risen to normal with continued parenteral vitamin D therapy, but the phosphatase remained high (see Fig.).

Discussion

The response to the parenteral injection of a dose of vitamin D which was ineffective by mouth indicates failure of absorption of vitamin D in our patient. This failure was not due to the increased steatorrhoea produced by the experimental conditions, since these conditions did not obtain before the experiment was begun, when the patient had been receiving the same dose of the vitamin while on a low-fat diet. Absorption of the vitamin at this time would have affected calcium absorption during the experimental period, since the action of vitamin D even in small doses is a prolonged one (Hannon *et al.*, 1934), so that apparently even without massive steatorrhoea absorption of the vitamin was defective. We were not able, as originally planned, to determine whether absorption of the vitamin occurs in the absence of fat in the bowel.

On the basis of our observations certain recommendations may be made. Ordinary doses of vitamin D may be ineffective in the prevention of osteomalacia in steatorrhoea. In the treatment of this condition parenteral therapy with ordinary doses of the vitamin is effective; oral therapy requires very large doses and is at best uncertain. Large amounts of calcium are necessary to replenish the stores. The patient may absorb 1 g. of calcium daily, equivalent to 7.7 g. of calcium lactate, and may even absorb much more (Starr and Gardner, 1930). It should be remembered, too, that approximately 13.5 g. of fatty acids combine with 1 g. of calcium, and it is possible that some calcium becomes unavailable by forming calcium soaps, so that, though the fat intake need never be severely limited except for diarrhoea, it should be as low as is compatible with a palatable diet when steatorrhoea is complicated by osteomalacia. Possible deficiencies of other fat-soluble vitamins need also to be treated.

Summary

A case of osteomalacia secondary to steatorrhoea is described. The bone disease progressed despite treatment with a low-fat diet and vitamin D and calcium supplements. On a daily intake of 70 g. of fat, 4.6 g. of calcium, and 12,000 i.u. of vitamin D orally the patient retained 1.9 g. of calcium in 16 days. With the same dose of vitamin given intramuscularly she retained 6 g. of calcium in 16 days. Apparently a failure to absorb vitamin D occurs in osteomalacia due to steatorrhoea.

We are indebted to Mr. J. R. P. O'Brien and the Nuffield Department of Clinical Biochemistry for the blood and faecal fat analyses and to the nursing staff of Collier Ward for their willing co-operation. We wish to thank Miss Sheila V. Haddacks for arranging the diets during the experimental periods.

SUPERIOR MESENTERIC ARTERIAL OCCLUSION

RECOVERY WITHOUT RESECTION

BY

W. GARDEN HENDRY, M.B., F.R.C.S., F.R.C.S.Ed.
Surgeon, E.M.S. L.C.C. Northern Hospital,
Winchmore Hill, London

In the pre-heparin era Whittaker and Pemberton (1938), in a discussion of 60 cases of superior mesenteric arterial occlusion, cited only one case with spontaneous recovery which later, coming to necropsy from an unrelated cause, was proved to have obliteration of the superior mesenteric artery. They also quoted Dye as having had three cases clinically diagnosed as mesenteric thrombosis, in which, on death from unrelated causes, obliteration of that artery was found at necropsy. However, since the introduction of heparin therapy, Jorpes (1946) quotes Ravdin as having two spontaneous recoveries, and Rudberg as having one in which the intestine looked viable and was not resected.

Spontaneous Recovery in Case Management.—The incidence of spontaneous recovery is impossible of assessment from the data available, as a number of cases undiagnosed and untreated will recover; but that a definite percentage do recover is certain, and this should be borne in mind when one is confronted with haemorrhagic infarction of the small gut that is still apparently viable. Especially is this so now, for while in the past the mortality rate of resected cases was 84.2% (Whittaker and Pemberton, 1938) and 83% (Cokkinis, 1926), the rate has no doubt dropped considerably in early cases since the introduction of heparin. —for example, Jorpes (1946) quotes Murray and McKenzie as having six resections with four recoveries.

Aetiology.—Cases of arterial occlusion can be immediately divided into embolic and thrombotic, and most of those in the literature would seem to be due to the latter phenomenon in local arterial disease—a very common condition, whether it be an atheroma, an arteriosclerosis, or a thrombo-angiitis obliterans. Even in cases of degenerative heart disease a thrombosis from associated arterial disease is more likely than an embolism, though in valvular disease of the heart embolism of course does occur. In the following case, with no evidence of embolism and with widespread peripheral arterial degeneration, thrombosis is very probably the correct diagnosis.

Addendum to Accepted Pathology

It is puzzling that a part with so much collateral circulation is so readily subject to infarction, and it has been suggested (Boyd, 1946) that the intense spasm of the gut in response to the local anaemia isolates the segment from the neighbouring circulation, while Cokkinis (1926) avers that infarction takes place when the secondary spreading thrombosis reaches the distal arterial arcade and blocks the vasa

recta. It would seem to be more in line with vascular pathology to suggest that in response to a local thrombosis a state of severe arterial spasm or "stupor" results in the distal arterial tree from a local vasoconstrictor reflex. This would at once place emphasis on treatment by such measures as restoration of the blood pressure by replacement of circulating fluid, moderate heat, and adequate morphine—in themselves powerful methods of overcoming the generalized vasospasm associated with the profound shock found in this condition. Locally, in the viable cases under discussion, an excision of the thrombosed segment of artery should be undertaken, or, if this is impracticable, a periarterial sympathectomy of the main trunk of the superior mesenteric artery. In post-operative care heparin, of course, will always be added to minimize the extent of the secondary thrombosis.

It is perhaps relevant, before leaving this subject of arterial spasm, to refer to the exhaustive account by Cohen (1944), who, studying peripheral vessels, could find no evidence of a sympathetic reflex and little evidence that periarterial sympathectomy has any effect on vascular spasm; nor did he find that arteriectomies had any dramatic effect on the return of distal pulses—in fact, he pointed out that no vasoconstriction occurs in the deeper vessels of an extremity on stimulation of the sympathetic nerve. However, in the case of the splanchnic area, conditions are very different, and the importance of vasoconstrictor fibres is very great; in fact, the splanchnic bed forms the most important part of the peripheral resistance (Wright, 1945).

Case History and Course

The patient, a retired bank clerk, aged 64 years, was admitted at 4 p.m. on Aug. 19, 1947. There was no previous history of illness of note. The patient had always been a healthy man, but had been on a pension for several years on account of "gout." The family history revealed nothing relevant. He was awakened at 5 a.m. on Aug. 19 with abdominal colic which made him roll about the bed. He had breakfast at 8 a.m., when the pains became worse, and he vomited at 10 a.m. and again at midday, since when he had been retching. His bowels had not opened since the onset of the pain, but previously they had been quite regular. General interrogation revealed that he had had palpitations both at rest and on exertion and that for several years he had noticed shortness of breath on stair-climbing. There was no swelling of the ankles. He had had frequent severe frontal headaches and some frequency and difficulty of micturition.

On examination the patient was seen to be a rather pale elderly man with slightly cyanotic lips; he was not in obvious pain. The temperature was 95° F. (35° C.), pulse 120, with very poor volume; the tongue was very dry, and the breath faecal-smelling. The central nervous system revealed nothing abnormal. The lung fields were clear. The heart was not clinically abnormal. The blood pressure was 70/50. The peripheral arteries were tortuous and thickened in both upper and lower extremities. The abdomen moved freely on respiration; there was no rigidity or distension, but a generalized ill-defined tenderness was present. There was a distinct rebound tenderness even though the patient was well under the influence of morphine. Shifting dullness could be elicited, and auscultation revealed vigorous widespread audible peristalsis. Per rectum the prostate was felt to be somewhat enlarged, but there was no rectal tenderness at the tip of the finger. The urine contained a trace of albumin and of blood. A first enema produced a few flecks of faeces and no flatus. A second enema after half an hour gave a good faecal result, and the enema fluid looked as though it was blood-stained. Two hours after admission the patient vomited a faecal-smelling light-coloured vomit. A plasma drip was started and operation was decided upon.

Operative Findings (Cyclopropane-oxygen anaesthesia).—A right lower transverse abdominal incision revealed a normal appendix and 2 to 3 pints (1.1 to 1.7 litres) of

blood-stained free fluid which was *spontaneously coagulable*. In the upper abdomen two upper loops of jejunum were markedly engorged and contracted, with a mesentery grossly oedematous right up to the border of the intestine. The mesentery was at least 1 in. (2.5 cm.) thick. The bowel was in a condition of haemorrhagic infarction and seemed still viable, so the abdomen was closed without intervention, as it was considered that a patient with a systolic blood pressure of 70 mm. Hg was unfit to withstand any extensive intra-abdominal procedure.

Post-operative Course.—Continuous gastric suction was started and fluids were given by mouth from the first day. Slow intravenous glucose-saline was given to attain rehydration. In addition intravenous heparin, "liquemin" (Roche), 5 ml. (50 mg.), was given every five hours, which kept the capillary coagulation time between 10 and 20 minutes. This was continued for five days. On the first day the blood pressure was 114/64 and the suction fluid dark and foul-smelling. The intravenous fluids were continued. On the second day the blood pressure was 138/84, the suction fluid was clearing, and the intravenous fluids were still being given. On the third day the blood pressure was 138/84, and the suction and intravenous fluids were discontinued. On the fourth day the blood pressure was 152/90; there was no gastric residue and the patient was beginning to feel hungry. Nourishing fluids were started and the bowels opened normally. On the fifth day the blood pressure was 156/98; the patient was now feeling quite well and was taking a normal diet. Heparin was discontinued. From then on convalescence was uninterrupted, and the blood pressure finally remained at 150/90.

Comment

Diagnosis.—In retrospect I feel that the diagnosis could have been made with some confidence, for here was a patient presenting the picture of (a) really profound shock, (b) partial intestinal obstruction with repeated and progressive vomiting but with good peristalsis and an adequate result from two enemas, and (c) peritoneal irritation evidenced by marked rebound tenderness and the presence of clinical free fluid. The blood-stained second enema should really have clinched matters, and is of interest as denoting that the vigorous peristalsis had propelled blood-stained contents of the small intestine into the colon sufficiently to be evacuated with the enema. This picture in a man with obvious peripheral arteriosclerosis was very suggestive indeed.

Differential Diagnosis.—Such profound shock is likely only in the following conditions: (1) *Coronary thrombosis*, which was ruled out in this case as all the signs were so obviously abdominal; (2) *Acute pancreatitis*, which would not be associated with progressive vomiting or with a blood-stained enema and in which the pain is much more severe and constant in character; and (3) *Long-loop strangulation*, which would present a very similar picture but in which some previous operative intervention would probably be noted and the second enema would be unlikely to produce any result, but certainly not a blood-stained one.

The Causation of Shock.—In this case there is little doubt that the shock was due to the escape from the circulating blood of a large quantity of plasma by transudation from damaged intestinal and mesenteric capillaries, and approximately 3 pints (1.7 litres) of spontaneously coagulable fluid was evacuated from the abdomen.

According to the literature, shock and blood-stained intra-peritoneal fluid are common findings in these cases. I would suggest that really massive plasma infusions of 2 to 3 pints (1.1 to 1.7 litres) should be given immediately and be continued till the blood pressure reached a satisfactory level and haemo-dilution to 110% Hb was obtained, as the condition of this patient was certainly closely allied to the condition of shock in burns.

Summary

The aetiology and pathology of superior mesenteric arterial occlusion are discussed, and arterial "stupor" is suggested as being of importance.

The history, clinical findings, and course of a case of "spontaneous recovery" are detailed and the diagnosis and differential diagnosis noted.

The causation of shock is discussed and suggestions are made as to its treatment.

CHEMOTHERAPY OF INFECTED URINES IN PARAPLEGIA

BY

PETER T. J. C. P. WARNER, M.B., B.S.

(From the Central Pathology Laboratory, Stoke Mandeville Hospital, and the Bland-Sutton Institute of Pathology, Middlesex Hospital)

During the routine bacteriological examination of urines from patients with complete transverse lesions of the spinal cord and suffering from chronic cystitis it was noticed that a large percentage of the lactose-fermenting colonies grown, which on staining were seen to be composed of Gram-negative bacilli, were distinctly mucoid in appearance. They occasionally contained a bubble of gas trapped in the substance of the colony, which suggested that the organisms were *Bact. aerogenes* rather than *Bact. coli*. This observation, together with the increasing interest in the treatment of urinary infections with streptomycin and penicillin, prompted this investigation. Fifty strains of coliform organisms from the above-mentioned paraplegic patients were tested to determine the incidence of *Bact. aerogenes* and their sensitivity to penicillin, streptomycin, and sulphathiazole.

Materials and Methods

Fifty strains of these Gram-negative organisms, which produced acid and gas from a fluid medium containing 1% lactose, were primarily isolated from the routine litmus-lactose-agar plate cultures of paraplegic patients' urines. These were either the predominating or the only organisms grown. A single colony was picked off the plate, spread on a second plate, and reincubated; after incubation overnight at 37° C. a single colony was picked off the second plate and inoculated on a broth-agar slope in a cotton-wool-plugged centrifuge tube (4 in. × 5/8 in. —10.2 cm. × 1.6 cm.). After incubation overnight the slopes were covered with sterile liquid paraffin as described by Morton and Pulaski (1938), who showed that organisms kept under such conditions did not alter their characteristics. After six months at room temperature all cultures were viable. During this period the organisms were subcultured and subjected to biochemical tests for identification and tests for sensitivity to streptomycin, penicillin, and sulphathiazole.

The stock cultures were subcultured on to litmus-lactose plates to check purity. The following day one colony was picked off into peptone water. The peptone water was

then incubated at 37° C. for 4 to 6 hours, when subcultures were made into the following media: (1) Clark and Lubs's glucose phosphate medium, (2) Koser's citrate broth, (3) McConkey's broth. The first two were incubated at room temperature and the latter at 44° C. The peptone-water cultures were retained and incubated at 37° C.

Indole Test.—This was performed on the original peptone-water cultures with equal parts of culture and Ehrlich's reagent and one drop of saturated potassium persulphate. The test was performed at 3, 5, and 10 days. All positive reactions were obtained on the third day and remained positive on the fifth and tenth days.

Voges-Proskauer Reaction.—Glucose-phosphate medium was used and incubated at room temperature, and the α-naphthol test of Barritt (1936, 1943) was used. The test was performed at 48 hours.

Methyl-red Test.—Glucose-phosphate medium was used and incubated at room temperature. The test was performed at 3 days.

Growth in Citrate.—Koser's citrate was inoculated with a straight wire from the peptone-water culture and incubated at room temperature. The cultures were not discarded for 10 days, but if growth occurred it was evident in the first 48 hours.

Gas at 44° C.—McConkey's broth was inoculated after being warmed to 44° C. The cultures were incubated in a water-bath running at 44 ± 1° C.

In the case of four anomalous cultures the tests were repeated; the ability to grow in citrate was also tested at 37° C., with a normal as well as a large inoculum, all with the same results.

Penicillin and Streptomycin Sensitivity Tests.—The appropriate concentration of the drug was diluted in infusion broth and approximately 1 ml. of this solution transferred to sterile cotton-wool-plugged tubes, 3 in. × 1/4 in. (7.6 cm. × 1.25 cm.). These were inoculated with a drop of broth culture of the organisms under test and incubated overnight. The following morning the tubes were examined with the naked eye for growth.

Sulphathiazole Sensitivity Tests.—Poured-broth-agar plates were used with the appropriate concentration of sulphathiazole added and containing laked horse's blood to neutralize sulphonamide antagonizers, as described by Harper and Cawston (1945).

Results

Table I shows the incidence of the different types of organisms and their biochemical reactions. Table II shows the results of the sensitivity tests. Those organisms which were resistant to 500 units of penicillin per ml. were subjected to a further series of tests for sensitivity to penicillin; the results of these and of the tests for sensitivity to sulphathiazole are shown later.

The results of the streptomycin-sensitivity tests show that 9 out of 12 (75%) of the strains of *Bact. coli* are sensitive

TABLE I

Organism	No. of Strains in Each Group	Per cent Incidence	Gas at 44° C.	Methyl-red Test	Indole Production	Voges-Proskauer Test	Utilization of Citrate
<i>Bact. coli</i>	12	24	+	+	+	—	—
Irregular <i>Bact. coli</i> type I*	2	4	—	+	+	—	—
<i>Bact. aerogenes</i>	32	64	—	—	—	+	+
Unclassified	4	8	—	—	—	+	—
Total	50	100					

TABLE II

Organism	No. of Strains in Each Group	μ g. of Streptomycin per ml. Inhibiting Growth				Units of Penicillin per ml. Inhibiting Growth					
		<1	1-8	8-16	16-32	50-75	75-100	100-200	200-500	>500	
<i>Bact. coli</i> ..	12	4	5	0	3	1	9	0	2	0

to less than 8 μ g., and 3 out of 12 (25%) of the strains to between 16 and 32 μ g. of streptomycin per ml.; 46 out of 50 (92%) of all the organisms are sensitive to less than 8 μ g., and the remaining 8% to between 16 and 32 μ g. per ml. Out of 32 strains of *Bact. aerogenes* 30 (94%) will grow in a concentration of 500 units of penicillin per ml.; whereas 10 out of 12 (83%) of *Bact. coli* strains are inhibited by 100 units of penicillin per ml. Seventy-six per cent of all strains grow in 200, 68% grow in 500, and 24% are inhibited by 100 units of penicillin per ml.

Forty-six (92%) of the strains resisted 50 mg. of sulphathiazole per 100 ml.; 4 (8%) were sensitive to 1 mg. per 100 ml. Of the 4 that were sensitive 2 were *Bact. aerogenes* and 2 *Bact. coli*.

The 34 strains (30 *Bact. aerogenes* and 4 unclassified) which were resistant to 500 units of penicillin per ml. were tested in 11 higher concentrations to a maximum of 100,000 units per ml. Twenty-five were inhibited by concentrations of between 1,000 and 5,000 units per ml., but 6 were resistant to 50,000, and 1 strain to 100,000, units per ml.

Discussion

It is generally agreed that *Bact. aerogenes* is found most commonly in soil and on vegetation and when encountered in public-health work is not necessarily considered indicative of recent excretal contamination of water and foodstuffs. But Cruickshank (1931) states that it can be isolated from the stools of the majority of normal people if enrichment methods are used, and Gray (1932) found it in 37 out of 40 samples of faeces from 10 normal people. Other workers give figures from 0 to 26%.

However, *Bact. aerogenes* is not infrequently found in urinary infections. This organism has been reported as constituting 63% (Burke-Gaffney, 1932) and 52% (Burke-Gaffney, 1933) of urinary coliform organisms in Tanganyika territory, 50% of urinary Gram-negative bacilli (Hill *et al.*, 1929) in the U.S.A., and 39% of all urinary organisms from patients with "neurogenic" bladders (Petroff and Lucas, 1946) also in the U.S.A. The latter workers, however, do not mention *Bact. coli* in their list of percentage incidence of organism although it does appear in their tables, so it is impossible to calculate the proportion of *Bact. aerogenes* to *Bact. coli* in their series of 87 cases. It thus appears that the incidence of *Bact. aerogenes* in the series of patients reported in this paper is of the same order as that in groups of patients with urinary infections described by other workers.

The organism called "Irregular type I" resembles *Bact. coli* in its primarily intestinal origin and biochemical characteristics, differing only in that it does not produce gas from McConkey's lactose broth. It also resembles *Bact. coli* in being comparatively sensitive to penicillin (see Table II). The group labelled "unclassified" in the tables resembles *Bact. aerogenes* biochemically except that it does not utilize citrate. The resistance of this group to penicillin and streptomycin is of the same order as that of *Bact. aerogenes*.

It is clear from the results of the sensitivity tests (see Table II) that all the organisms examined here are fairly susceptible to streptomycin irrespective of their type. However, all the *Bact. aerogenes* and the unclassified organisms are sensitive to 8 μ g. or less per ml., whereas 3 out of 12 *Bact. coli* strains and 1 out of 2 of the related irregular types are insensitive to 16 μ g. but sensitive to 32 μ g. per ml. Thus perhaps *Bact. coli* is less sensitive to streptomycin than is *Bact. aerogenes*. In any event 46 (92%) of the strains of coliform organisms lie within, and the remaining 8% are doubtfully within, the therapeutic range of streptomycin.

It is difficult to foretell from these *in vitro* tests how successful streptomycin is likely to be in treatment, because the failures in these cases appear at times to be due to the rapid development of resistance by the organism to the drug. Despite this complication, however, Petroff and Lucas (1946) consider that their paraplegics with "neurogenic" bladders benefited from treatment with the drug, although their paper in some respects is not altogether conclusive. It may well be that streptomycin will become a valuable weapon in these infections, but from my experience it is obvious that as high dosages as possible should be tried. Starting the course with a dose considerably greater than the subsequent ones should be borne in mind. The purpose of these precautions is to ensure that the responsible organism is never subjected to a concentration of streptomycin below the bactericidal or bacteriostatic level—that is to say, to those conditions that are likely to increase its resistance to the drug. We are assuming that the development of resistance is the result of contact with the drug and not due to the presence of a small percentage of naturally resistant strains. This point has not been decided, and no convincing evidence exists for either view.

Since Peeney (1947) advocated the use of penicillin in Gram-negative bacillary infections of the urinary tract and Helmholz and Sung (1944) found that *Bact. aerogenes* was relatively insensitive to penicillin, it seemed important to determine here the incidence and resistance of that organism to penicillin, for a high incidence of penicillin-resistant organisms, either widespread or in any particular locality or group of patients, would be a contraindication to the routine use of the drug in treatment.

In this series penicillin divides the organisms into two fairly clearly defined groups: all but two strains of *Bact. coli* and the associated irregular *Bact. coli* are sensitive to 100 units of penicillin per ml., whereas the *Bact. aerogenes* and the associated unclassified organisms are resistant to 200 units per ml. of penicillin, above which level Peeney (1947) suggests that they are not likely to respond to penicillin therapy. Thus resistance to penicillin may be a characteristic of the *aerogenes* group of organisms, and the incorporation of penicillin in an appropriate concentration in a medium might be suitable for isolating *Bact. aerogenes*. In view, then, of the high incidence of *Bact. aerogenes* in this and other series of cases and the undoubted resistance of this organism to penicillin, it is obvious that this drug cannot be used for the routine treatment of urinary infections involving coliform organisms, especially if we accept Peeney's (1947) suggestions without reserve. Moreover, 76% of the total number of coliforms in this series are resistant to penicillin according to his criteria. Under the circumstances penicillin treatment would be only occasionally successful in these infections: and then only under full bacteriological control.

It has been assumed that it is necessary to obtain only the concentration of penicillin in the urine which *in vitro* will be bactericidal to the organisms involved; this obviously is not the case, for the organisms must be causing

the mischief in the tissues of the urinary tract. This is evident from the polymorphonuclear leucocytosis that occurs, and it is generally accepted that these infections are blood-borne or spread by lymphatics (Walker, 1922, 1930). This worker and others have demonstrated organisms and cellular infiltration in the tissues of the urinary tract. Of course the mischief may not be very deep-seated and the concentration of penicillin in the tissues of the urinary tract may be higher than elsewhere owing to the diffusion of that substance from the urine, but even if this is the case the tissue concentration must be lower than the urinary, though it may be greater than the blood. Thus we see that it is impossible to relate directly the urinary level and the sensitivity of the organism to penicillin *in vitro* and in this way determine whether a urinary infection is likely to respond to treatment with a certain dosage of penicillin; this argument will apply to any other drug. The final court of appeal, as always in this particular type of problem, will be clinical trial and error of various dosage systems given under standard conditions and related to the *in vitro* drug sensitivity of the organisms.

With ordinary doses it is practicable to maintain an average level of 200 units per ml. of penicillin in the urine, but theoretically there is no reason why 2 or more million units of penicillin should not be injected every three hours, though even under the best conditions this dosage would be inadequate for one-quarter of the *Bact. aerogenes* and nearly one-fifth of all the organisms in this series (as indicated by the extended penicillin sensitivities listed in the results). When penicillin becomes cheaper and even more readily available it may be possible to treat most Gram-negative urinary infections with it. In any event, it is already useful for treating urinary infections associated with Gram-positive organisms.

Of the coliforms examined 46 out of 50 (92%) resist 50 mg. of sulphathiazole per 100 ml. using the method described above. This is in approximate agreement with the findings of Neter and Clark (1944) but not with Strauss and Finland (1941), who used a synthetic medium. There do not seem to have been any published reports of the correlation of *in vitro* sensitivities with clinical results, but the figure seems high. Bearing in mind the possible site of action of the drug, one must pause to consider how much value the sulphonamides are in urinary infections with Gram-negative bacilli. However, Nathan (1947) reports favourably on them for treating paraplegic patients with suprapubic cystostomy.

Summary

Of 50 strains of lactose-fermenting coliform organisms isolated from infected urines of paraplegic patients 32 were *Bact. aerogenes*, 12 were *Bact. coli*, 2 were irregular types of *Bact. coli*, and 4 were unclassified. The incidence of *Bact. aerogenes* in this group does not differ greatly from that in other patients with urinary infections.

All the organisms were sensitive to streptomycin, and all but 4 resistant to 50 mg. of sulphathiazole per 100 ml.

Bact. aerogenes and the unclassified organisms were relatively resistant, and *Bact. coli* and its irregular types relatively sensitive, to penicillin. The high incidence of *Bact. aerogenes* and its undoubted resistance to penicillin does not favour the use of the drug at present in the routine treatment of urinary infections by Gram-negative bacilli. In this series it was concluded that at least one-fifth of all the organisms were too resistant for penicillin treatment in high dosages and three-quarters too resistant for ordinary dosages.

The results are discussed and their impact on the treatment of urinary infection considered.

My thanks are due to Prof. J. McIntosh and Dr. F. R. Selbie for advice and criticism, and to Lady Florey and Prof. J. McIntosh for supplies of streptomycin.

CARDIAC MURMURS IN INFANCY

BY

NANCY COX, B.M., B.Ch., D.C.H.

(From the Institute of Social Medicine, Oxford)

Much has been written about cardiac murmurs in older children, but relatively little work has been done on their incidence and manifestations in infant communities. Von Reuss (1929) states that any definite murmur heard in a child who is quiet should be regarded as evidence of congenital heart disease and that murmurs at this age are very rare. On the other hand Holt (1940) states that 50% of all children have a functional murmur at some time. Lyon and others (1940) examined 7,000 newborn infants in the obstetrical wards of a general hospital and found that 147 (1.9%) had apical systolic murmurs; two of these died of congenital heart disease, and in 14 of the 88 who were re-examined six months later the murmurs were still present.

Since the Child Health Survey of the Institute of Social Medicine was initiated at Oxford three years ago 630 children have been enrolled, and the oldest have now been under observation for three years; 520 children remain in the survey at present, the 110 defaulters belonging chiefly to families which have moved to other areas owing to the housing shortage. The defaulters were followed up for periods varying from six months to two and a half years. It should be emphasized that this is not a hospital series but a sample of ostensibly healthy children drawn from all social classes, whereas the authors quoted either employed a hospital population or have not stated how their samples were obtained. Of the 630 children, 32 (5%) have been noted as having a murmur at some time. It was thought that it would be interesting to investigate the time of development of these murmurs and their subsequent history so far as at present observed.

In the course of the main health survey a full physical examination is made at regular intervals; first at the age of 6 weeks or less, then at 3, 6, 9, and 12 months, with subsequent examinations at six-monthly intervals. It has not always been possible to adhere strictly to the exact intervals owing to illnesses or other difficulties. Three observers, working in succession but observing the same routine as closely as possible, have carried out examinations on children first seen at infant welfare centres or at mothercraft clinics. All the children have had their chests examined radiographically, first at the age of 6 months and

hereafter at six-monthly intervals, except in a few instances where some unforeseen occurrence has prevented this.

Development of the Murmurs

The 32 children with murmurs have been grouped according to the age at which the murmurs were first noted; the murmurs have been described as "transient" if heard at only one examination and not subsequently; "temporary" if heard at more than one examination and then apparently disappearing; "persistent" if heard at more than one examination and persisting up to the most recent examination.

Table Showing Development of the Murmurs

Age in Months when Murmur First Noted	Transient Murmur	Temporary Murmur	Persistent Murmur	Present for First Time and Not Yet Re-examined
0-2	3	1	1	0
3-4	1	1	1	1
6-7	0	0	1	0
9-10	3	0	2	1
12-13	1	0	2	2
18	1	1	6	0
24	2	0	1	0

The murmurs recorded were all systolic in time, and it may be noted that Owen and Kingsbury (1924) state that a diastolic murmur is never heard in a newborn infant. The murmur was often heard best when the child was lying down, and was usually loudest at the apex; it was most commonly conducted over the whole praecordium, but in some cases it was confined to the left border of the sternum. Three murmurs were specifically described as cardio-respiratory.

Some of the following data may prove relevant to the presence or absence of murmurs, but the cases are as yet too few to allow any conclusions to be drawn.

The ante-partum health of the mother was good in 21 cases, in the remainder the illnesses recorded were cystitis 1, ulcerated mouth 1, anaemia 1, ante-partum haemorrhage 1, toxæmia 1, vomiting 1, and giddiness 1; in three the health was recorded as "only fair." The birth weight of one of the children was only 4 lb. (1.8 kg.); the others varied between 6 lb. and 9 lb. 2 oz. (2.7 and 4.1 kg.). The sex distribution was unequal—23 boys and 9 girls. The general physical condition of the children was noted as "only fair" or "poor" in 13 out of the 32, without any specific diagnosis being attached. According to the Registrar-General's classification of social groups which depends upon the father's occupation, one of the 32 children was in social group 1, four were in social group 2, 21 in social group 3, three in social group 4, and three in social group 5. Group 3 has been the predominant single class from which the babies have been enrolled.

Haemoglobin estimations were made in only six of these children, and these gave figures of 60%, 82%, 85%, 88%, 96% and 106%. The haemoglobin estimations were discontinued because we were anxious not to undermine the confidence of the children, and those subjected to the test seemed to remember their visit unfavourably; furthermore, the mothers were not always very willing to consent to the taking of blood samples, and in a long-term survey such as this it is especially important not to risk the default of any more babies than can be helped. The child with the lowest recorded haemoglobin (60%) was treated with iron, and when last seen, while still under treatment, the murmur had become very much fainter.

The x-ray examination of the chests in 20 out of 29 of the children showed considerable variation in respect of size or shape of the mediastinal shadow, which my colleague Dr. F. H. Kemp commented upon; but whether the variations are significant or whether they are within the wide range of normal variability manifest at this age has yet to be determined. The mediastinal shadow in infancy shows wide variations not only as between one baby and another but also in the same baby in

successive radiographs taken at intervals of only a few seconds. Three of the children in this series were not radiographed.

Discussion

A long follow-up of these cases should provide further clinical data on the significance of the cardiac murmurs observed, and this report can be regarded only as preliminary. The knowledge that a murmur has been present since infancy may be of value to the individual, as it will assist in the differential diagnosis from rheumatic carditis at a later age, and in the absence of other signs or symptoms it may then be possible to allow normal activity, which might not otherwise seem justifiable.

It is apparent from the material studied that some murmurs are present from birth and others appear later. Those already present at the first examination and disappearing later may be due to the changes taking place during the adaptation from foetal to post-natal life. Transient or temporary murmurs may also accompany anaemia or may be exocardial in origin. Persistent murmurs either may be due to relatively insignificant congenital defects or may accompany the more important lesions.

It is noteworthy that 23 out of the 32 murmurs were not detected until the age of 9 months or later, and that six of those appearing at 18 months have persisted. One child who had a murmur first detected when she was 9 months old is now 2½ years old and has a loud persistent murmur with a faint palpable thrill over the pulmonary area, but no symptoms. It is possible that increased activity with crawling and walking may bring out defects not previously detectable.

In only one case in the series was cyanosis observed. It was noted at birth, a murmur was detected soon after delivery, and the mother was informed that the child had a congenital heart lesion. The cyanosis lasted only a few hours, but the murmur was present and clearly audible at each routine examination until the age of 1 year, when it was hardly perceptible. The child has been particularly healthy and active since she came under observation. In view of the fact that murmurs do disappear and that there may be no associated symptoms, it would seem advisable not to alarm mothers unduly. In the case described the mother had waited 12 years to have a child and was then given the impression that the child would be a permanent invalid. One other child showed some suggestion of dyspnoea on exertion. Except in the case of the child with anaemia, who had been suffering from diarrhoea for several weeks, there was nothing to suggest that the development of a murmur was ever a consequence of a specific illness. All the other children with murmurs appeared healthy, and no obvious congenital abnormalities were found affecting other structures.

Summary

In a routine periodic examination of the heart in 630 infants systolic murmurs were detected in 32 (5%).

Some were present at the first examination—i.e., before the sixth week—and later either disappeared or persisted; others appeared for the first time at the second or subsequent examinations, some of these disappearing and others persisting.

In 22 cases the murmur was not detected until the age of 9 months or later.

With the exception of one case in which a thrill in the pulmonary area subsequently developed, and another in which there was some suggestion of dyspnoea on exertion, no associated symptoms or signs were recorded.

No correlation between clinical findings and radiographic appearances could be established.

I am indebted to Prof. J. A. Ryle, to Drs. Allen-Williams and Helen Morley (my predecessors in the survey), and to all my colleagues in the Institute of Social Medicine for their assistance and

advice. Thanks are also due to the medical officers and health visitors of the Oxford City Health Department for their co-operation, and to all the mothers for their participation in the survey.

Medical Memoranda

Acute Lymphatic Leukaemia Presenting with Skin Lesions and Mastoiditis

It is exceptional for skin lesions to appear as the first or even as an early sign of leukaemia, although examples have been reported by Ketron and Gay (1923), Boardman (1928), and Wintrobe and Mitchell (1940). The paucity of published literature on this subject prompted the recording of the following case.

CASE REPORT

A woman aged 65 was admitted to hospital on Nov. 7, 1946, with a history of pains in the ears and deafness for three weeks and a more recent history of bilateral otorrhoea. Despite difficulties owing to deafness and her critical state it was ascertained that her health had been failing for some time and that within the previous three months she had developed a rash over her body.

On admission she was gravely ill with pronounced anaemia and slight icterus. Her gums were hypertrophied and bled readily, and there were scattered loose stumps of carious teeth in both jaws—accounting for the presence of pathologically enlarged submental and submaxillary nodes. There was evidence of bilateral mastoiditis. Over the trunk and proximal regions of the limbs there were numerous brown-grey plaques varying in size from 0.25 to 3 cm. in diameter. The majority projected above the skin surface, and though some were deeply situated none were adherent to bone. The papules were not painful, did not itch, and were not tender. There was some bruising of the legs, but purpura was absent until shortly before death. Apart from a marked thoracic kyphoscoliosis and a small plaque on the right fundus physical examination was negative.

A blood count showed: haemoglobin, 48%; red cells, 2,500,000; white cells, 1,300; platelets, 67,500. A biopsy revealed lymphadenosis cutis, a lymphatic leukaemic deposit in the skin. Sternal puncture verified the diagnosis of acute lymphatic leukaemia in an aleukaemic phase.

The patient went steadily downhill and died on Nov. 23. Necropsy was carried out, but revealed no evidence of leukaemic infiltrations except in the skin. There was no involvement of any of the nodes in the various groups throughout the body.

COMMENTARY

The skin lesions associated with leukaemia may be subdivided into (1) non-specific—sometimes known as leukamids—including such conditions as herpes zoster, purpura, prurigo, etc., and (2) lesions specific for the disease and composed of infiltrations by the cell types. Forkner (1938) states that the second group conforms to the following types. In myelogenous leukaemia the lesions consist of macules, papules, or plaques, sharply circumscribed, brownish to bluish in colour, and chiefly involving the trunk. The lesions are not painful and do not itch. Ulceration with local loss of tissue and possibly haemorrhage may occur. The lesions associated with lymphatic leukaemia are: (1) Erythrodermia (l'homme rouge), which is characterized by subacute or chronic progressive reddening of the skin spreading gradually to involve a large area of the body surface. This may be accompanied by a sensation of chilliness owing to increased loss of heat, and itching may be a prominent feature. Scaling is found and regional or generalized lymph-node enlargement is not uncommon. (2) Universal leukaemia of the skin, which is an exaggerated generalized form of the above. (3) Circumscribed leukaemia of the skin, where the lesions are usually well-defined maculae, or are slightly elevated,

with a wide variation in size and colour from yellow to bluish-red. These are most commonly found on the face, neck, and dorsum of hands and are rarely numerous. Apart from slight burning, subjective sensations are absent.

The circumscribed skin lesions associated with myelogenous and lymphatic leukaemia differ only in their distribution, and the distribution of the lesions in the above case conforms more to the myeloid type. Lewis (1919) published a similar case, with mastoid disease and the blood picture of lymphatic leukaemia, as chloroma. Brannan (1926) states that this term cannot be used correctly unless green pigmentation is present in the tumour, and Kandel (1937) defined the term as being applicable to any tumour which is green when fresh. Jones (1939), in an extensive review of the literature, decided that chloroma presented itself in two clinical forms: (1) affecting children and characterized by rapidly growing bone tumours, and (2) an adult type in which a progressive anaemia and signs of leukaemia are more prominent. He believed, however, that in both types the two essential features are leukaemic changes in the blood and green tumour deposits in the bones. The term "chloroma" should therefore be confined to conditions with lesions which have a frankly green colour, and is not applicable to my case.

I am indebted to Dr. John Craig for permission to publish this case, to Dr. H. W. Fullerton for the haematological findings, and to Dr. W. M. Davidson for the necropsy report.

Severe Reaction after Penicillin

The following report of a severe reaction following penicillin injections may be of interest.

CASE REPORT

A Regular Army officer aged 32 was hit on the left ankle while playing hockey on Sept. 17, 1947. He consulted me ten days later for pain and swelling of the ankle, and feeling generally out of sorts. On examination his temperature was 101° F. (38.3° C.), and he had an obvious infected haematoma just above the left external malleolus. He was given an intramuscular injection of 100,000 units of penicillin (sodium salt, yellow) immediately and a further 100,000 units that night. The next morning the haematoma was incised under local analgesia and about 1 oz. (28.4 ml.) of thick pus evacuated. He was given two injections each of 100,000 units of penicillin on this day. On Sept. 29 he was given one further injection of 100,000 units. His general condition was now good. Locally much of the pain and swelling had disappeared. The leg was healed and normal by Oct. 5.

On the night of Oct. 10-11 he developed a severe widespread urticarial eruption with intense itching. He was seen in the morning and given "benadryl" capsules to take four-hourly. This controlled the irritation but made him feel so ill that the drug was stopped and ephedrine substituted. On Oct. 13 the urticarial condition was unchanged. He complained of anorexia and indigestion and vomited in the evening, when his temperature rose to 100° F. (37.8° C.).

On Oct. 14 his condition was worse. In addition to the previous symptoms he then complained of stiffness and aching in all his joints. Curiously, if he could provoke an urticarial reaction by rubbing or scratching his skin the joint symptoms were temporarily relieved. Ephedrine was without effect on his joints. Next day he became so stiff that he could hardly move; nor could he move his jaw to eat solids. The aching pain was very severe and was only partially relieved by tablets containing aspirin, phenacetin, and codeine. His evening temperature still rose to about 100° F. This was his worst day, and he slowly improved until by Oct. 21 he had completely recovered.

J. F. L. WALLEY, M.B., B.Chir.

The Ministry of Health reports that about 17,500 doctors and 16,000 nurses attended 506 showings of the film entitled "The Early Diagnosis of Acute Poliomyelitis."

Reviews

PHYSICAL EDUCATION

An Introduction to Physical Education. By Eugene W. Nixon and Frederick W. Cozens. Third Edition. (Pp. 251. 14s.) Philadelphia and London: W. B. Saunders Company. 1947.

The Administration of Health and Physical Education. By Jesse Feiring Williams, M.D., Sc.D., and Clifford Lee Brownell, Ph.D. Third edition. (Pp. 483; illustrated. 15s.) Philadelphia and London: W. B. Saunders Company. 1946.

The authors of the first work are, respectively, Professor of Physical Education, Pomona College, California, and Professor and Director of Physical Education, University of California: of the second work, respectively, Emeritus Professor of Physical Education, and Professor and Chairman of the Department of Health and Physical Education, Teachers' College, Columbia University. These offices alone are significant evidence of the importance which in America is attached to the subject of physical education, and it is a perpetual wonder to our transatlantic colleagues that no corresponding appointments are held in Britain, where it is hardly an exaggeration to say that our activities in this field have been limited to the enterprises of a few amateur enthusiasts. Further evidence is afforded by the general bibliography appended to the first volume. Of 315 references, Great Britain supplies only two—Prof. A. V. Hill's well-known contributions on muscular activity, which incidentally were published in the U.S.A.

We may expect more in the future, for the deeply ingrained traditional interest in athletics in Britain will always inspire individual workers. The post-war appointments in the spheres of social medicine and rehabilitation are perhaps the first steps towards a more widespread recognition of the necessity for physical education—and possibly in time the creation of a special Ministry. For this reason both works may be cordially recommended. The first, less comprehensive, may be regarded as an introduction; the second will prove a useful guide to those who may be in a position to organize and to administer, for in addition to a shrewd common-sense exposition there is much practical assistance in the form of diagrams of gymnasia, swimming-pools, and athletic tracks, as well as illustrations of specimen forms for the collection of information. This work should be in the hands of aspirants to the Diploma of Physical Medicine of our Royal Colleges, and both may be highly recommended to school medical officers.

ADOLPHE ABRAHAM.

TEXTBOOK OF OBSTETRICS

Principles and Practice of Obstetrics. By the late Joseph B. De Lee, M.D., and J. P. Greenhill, M.D. Ninth edition. (Pp. 1,011; 1,108 illustrations. 50s.) London and Philadelphia: W. B. Saunders Company. 1947.

De Lee's *Principles and Practice of Obstetrics* has long been a standard textbook for advanced students and one to which most obstetricians turn first when in doubt; indeed, it has been called "the obstetrician's Bible." The ninth edition is the work of Prof. J. P. Greenhill and is so altered as to be barely recognizable. Superficial changes in structure include a new type of binding and the arrangement of the text in two columns on each page. Both these features are attractive and make the volume less bulky and easier to read. There are also more fundamental alterations involving spirit and outlook. The original book was characterized by its practical nature and the reader was acutely conscious of the author's personality and clinical experience. Much of this has gone, and in its place has come a more scientific approach with more emphasis on the theoretical aspects of midwifery. Perhaps the change of authorship, as well as the advance of medicine, made this inevitable. In its own way and with its modern setting it is just as good a book, however: in losing an old friend we have made a new one.

The illustrations, always a striking feature of the book, are more numerous and are better than ever. The text has been completely revised and brought up to date, several authorities on special aspects of obstetrics having contributed or assisted. The chapter on analgesia and anaesthesia, as well as many

others, has been considerably extended. Those on the "Physiology of the Fetus," "Ante-partum Care," and "Post-partum Care" have been rewritten completely, and the additions include chapters on "Minor Disturbances of Pregnancy," "Premature Labor, Prolonged Labor or Post-maturity, and Missed Labor," "Fetal Erythroblastosis," "Care of Premature Babies," and "Circumcision." As in previous editions a careful and detailed description of obstetric operations and manœuvres is one of the most striking and valuable features of the book. At a time when efforts are being made to popularize the use of the metric system in this country it is interesting to find that the author panders to British conservatism by giving the dose of all drugs according to the imperial as well as the metric system.

No book is perfect, and, good as it is, this is no exception. Some methods of treatment described at length, such as the use of hydrostatic bags for placenta praevia, will in Britain be regarded as out of date, and those looking for a complete reference book will find some omissions. Nevertheless, few textbooks on obstetrics written in English can compare with it. This edition deserves and will undoubtedly receive an enthusiastic welcome, and will become as popular with the new generation of obstetricians as its predecessors were with the old.

T. N. A. JEFFCOATE.

HISTORY OF DRUGS

Drugs from Plants. By Trevor Illtyd Williams, B.A., B.Sc., D.Phil. Sigma Introduction to Science 10. (Pp. 119; 12 plates. 6s.) London: Sigma Books, Ltd. 1947.

The Sigma Introductions to Science series promises to be a notable addition to the already considerable volume of works of popular science. The second of the series, Berenhiun's *Science versus Cancer*, was a splendid example of what may be achieved by a medical scientist writing on his own subject for the general reader. Now comes another member of this series on *Drugs from Plants*. There are few subjects upon which the general public needs enlightenment so much as on drugs and their uses and limitations. Dr. Williams's little book will contribute to that enlightenment, especially as his approach is historical and he has wisely confined himself to a few important and representative plant drugs.

In the Introduction there is the inevitable reference to the Papyrus Ebers, followed by brief mentions of some of the writers on the materia medica in ancient times and some of the sixteenth-century herbalists. In the second chapter, on "Science and the Art of Herbalism," the author indicates the importance of active principles of plant drugs, of the experimental study of their effects, and of their standardization. The next chapter, on "The Kinds of Drugs Obtained from Plants," is particularly useful for the clear explanations of elementary chemical considerations. Then follow chapters on particular drugs—quinine, hashish, digitalis, penicillin, ergot, opium, cocaine, and miscellaneous drugs. The book ends with a chapter on "What of the Future?" in which the author refers to probable lines along which pharmacological research will develop. The chapter on penicillin is particularly to be recommended: it is an admirably concise and balanced account of a story that has been wildly distorted in the popular press.

So far, so good. The general reader will obtain from this book a good deal of useful, interesting, and well-presented information about the history of drugs, although the author does not perhaps sufficiently stress the fundamental difference between—to use Ehrlich's terminology—organotropic drugs, which are given for their effects upon an organ or system of the patient, and aetiologic drugs, where the patient is merely the vehicle for a drug aimed at his parasite. From the test of more searching standards of criticism, however, the book does not emerge so well, although the author in his preface deplores the inaccuracy of many popular scientific writings. For example, it is surprising to find in a work published in 1947 a repetition of the familiar legend of the Countess of Chinchona and quinine. This legend was completely exploded six years ago by the late A. W. Haggis in one of the most scholarly and significant studies in the history of pharmacy of recent years, and it is a pity that the author has overlooked it. Of Venice treacle the author writes that it was "said to have been devised by Dioscorides himself," although it was in fact always attributed to Nero's physician, Andromachus, as was indicated by

its pharmacopoeial name, Theriaca Andromachi. It is also stated that Venice treacle "enjoyed considerable popularity . . . as late as 1739, and possibly a good deal later." Why "possibly"? The facts are not difficult to find and were, as it happens, assembled by the reviewer in a paper published nearly two years ago. Theriac was not only popular but was an official preparation of the *Pharmacopoeia Londinensis* until 1788 and of the French *Codex* until 1908. Later on it is asserted that "Synthetic quinine cures malaria as effectively as crude extracts of cinchona bark." This sounds plausible enough, but has synthetic quinine ever in fact been used in the treatment of malaria? The statement that strychnine is "a general tonic and a valuable stimulant" is uncritical, though it must be admitted that it might be found in many medical textbooks. The name of Halsted, first professor of surgery at Johns Hopkins and one of the founders of American surgical science, is misspelt and he is described as "a New York dentist." Hyoscine is mentioned as a drug used in twilight sleep and "asthma cigarettes," but there is no reference to its more interesting property as the most effective of all drugs tested during the war in counteracting motion-sickness. Plate V is a reproduction of a wood-cut from the *Liber de Arte Destillandi* of Hieronymus Brunschwig. It would surely have been of some interest to indicate in the legend that the scene depicted is the preparation of theriac. Many similar faults of detail could be mentioned, but a major fault is that no bibliography is included—an inexcusable omission in any work which purports to give, at whatever level, a historical account of its subject.

N. HOWARD-JONES.

TREATMENT IN HEART DISEASE

Management of Common Cardiac Conditions. Edited by William G. Leaman, Jr., M.D., F.A.C.P. The American Practitioner Series. (Pp. 306; illustrated, 24s.) Philadelphia and London: J. B. Lippincott Company. 1947.

Twenty-four cardiologists, mostly Pennsylvanian, have contributed to this symposium. Like most editors of such works Dr. Leaman has found it difficult to balance the individual interests of his writers against the continuity of the whole, and the volume is selective rather than systematic. While most of the contributions are carefully expressed and well considered, there are several that do not refer to treatment at all, and in some others discussion of therapy and management is subsidiary. Specially noteworthy are the articles on congenital cardiovascular anomalies, subacute bacterial endocarditis, and pulmonary heart disease. In an admirable appraisal of the meaning of the electrocardiogram Dr. L. N. Katz echoes the feeling of all orthodox cardiologists when he writes that "the electrocardiogram is not a tool for the unscrupulous or a plaything for the erudite physician" but evidence that should never be considered separately from the clinical context.

While this book is often interesting, lack of co-ordination has unfortunately resulted in certain omissions. For example, one seeks in vain for guidance in the treatment of paroxysmal dyspnoea and its common precursor, hypertensive heart failure. The editor contributes the article on congestive heart failure, and though it is of exceptional interest he discusses only the use of the mercurial diuretics. The practising physician and the cardiologist alike will find much worth their attention and, in particular, some useful surveys; on the other hand the book is not sufficiently systematic for the student.

K. SHIRLEY SMITH.

The 1946 Year Book of Industrial and Orthopedic Surgery (H. K. Lewis, 21s.) forms a memorial to that indefatigable New England gentleman, Dr. Charles F. Painter, its editor, who died while the work was being prepared. There are several hundred abstracts of reviews taken chiefly from the English-speaking literature, as well as a large number of the more important illustrations to these articles. Although these are of course abstracts, it is all too often clear that much medical literature to-day contains about 15 ounces of rehash to every ounce of originality. Nevertheless, the present work contains much valuable information in a small space, and its value is greatly enhanced by the excellent illustrations. Future editions could be improved by including critical comment and abstracts of orthopaedic articles more representative of the non-English-speaking countries.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

The 1947 Year Book of General Medicine. Edited by George F. Hick, M.D., et al. (Pp. 784. 21s.) London: H. K. Lewis. Numerous aspects of the present-day practice of medicine are discussed.

Essentials of Fevers. By Gerald E. Breen, M.D., B.Ch., D.P.H., D.O.M.S. 2nd ed. (Pp. 351. 15s.) Edinburgh: E. and S. Livingstone. 1948.

A manual of "fevers" intended for students and young practitioners.

Diseases of the Nose, Throat, and Ear. By I. Simson Hall, M.B., Ch.B., F.R.C.P.Ed., F.R.C.S.Ed. 4th ed. (Pp. 463. 15s.) Edinburgh: E. and S. Livingstone. 1948.

An outline for the general practitioner.

Medical Cases Described for Nurses. By S. Locket, M.B., B.S., M.R.C.P. (Pp. 88. 6s.; paper covers, 4s.) Edinburgh: E. and S. Livingstone. 1948.

A brief introductory manual of clinical medicine intended for nurses.

The Secret Instrument. By Walter Radcliffe. (Pp. 83. 10s. 6d.) London: William Heinemann. 1947.

The early history of the midwifery forceps.

Guide to the History of Physical Education. By F. E. Leonard, A.M., M.D. 3rd ed. revised by G. B. Affleck, A.M., M.P.E. (Pp. 479. 27s. 6d.) London: Henry Kimpton. 1947.

A history of physical education throughout the world from the time of classical Greece.

Unipolar Lead Electrocardiography. By Emanuel Goldberger, B.S., M.D. (Pp. 182. 20s.) London: Henry Kimpton. 1947.

A monograph on unipolar electrocardiographic leads in the normal and abnormal heart.

A Manual of Otolology, Rhinology and Laryngology. By H. C. Ballenger, M.D., F.A.C.S. 3rd ed. (Pp. 352. 22s. 6d.) London: Henry Kimpton. 1947.

Intended particularly for students and general practitioners.

Nierenkrankheiten. Two vols. By the late Prof. Erwin Becher. Edited by Prof. F. Volhard. (Pp. 688; 358. No price.) Jena: Verlag von Gustav Fischer. 1944.

A textbook of diseases of the kidney.

Indice Bibliografico de Lepra. Vol. II (I-P; 1500-1944) (Pp. 1,430. No price.) Brazil: Sao Paulo. 1946

An index of references to leprosy.

Traitement de l'Emphysème des Dyspnées Scéléreuses de l'Angine de Poitrine. By Paul Cantonnet. (Pp. 275. 600 francs.) Paris: Librairie Maloine. 1948.

A monograph on the treatment of certain cardiac and pulmonary disorders.

Der Gestaltkreis. By Viktor von Weizsäcker. (Pp. 208. No price.) Stuttgart: Georg Thieme Verlag. 1947.

A contribution to gestalt psychology.

Cisti e Pseudocisti del Polmone. By G. Rizzi and O. de Lorenzi. (Pp. 344. No price.) Faenza: Fratelli Lega. 1947.

A monograph on congenital and parasitic cysts and pseudocysts of the lung.

Chirurgia Comune e di Urgenza. By Umberto Nobili. 4th ed. (Pp. 470. No price.) Milan: Ulrico Hoepli. 1947.

A textbook of emergency surgery.

Die Gynäkologischen Operationen. By Prof. Heinrich Martius. (Pp. 424. No price.) Stuttgart: Georg Thieme. 1947.

A textbook of operative gynaecology.

Les Acquisitions Médicales Récentes. By J. Rostand et al. (Pp. 316. 650 francs.) France: Editions Médicales Flammarion. 1947.

Papers on a variety of subjects in clinical medicine

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JANUARY 24 1948

MONEY AND FREEDOM

Reports from all parts of the country suggest that an overwhelming majority of doctors are radically opposed to the National Health Service Act in its present form. Medical men are convinced that this Act is the first and substantial step towards a whole-time State Medical Service. Even those who might be inclined to "give it a chance" see the grave risks of saying Yes. This Act is Mr. Bevan's revolution. Once the profession crosses the Rubicon there will be no retreat. Mr. Bevan will have the power by Regulation to make medical men whole-time servants of the State. Once in his Service we shall be powerless to do anything more than haggle over terms and conditions. As something like £120,000,000 will have to come out of State funds for the payment of Mr. Bevan's Service the Treasury will have the whip-hand in finance. Section 75 (3) states: "Any power conferred on the Minister by this Act to make Regulations shall, if the Treasury so direct, not be exercisable except in conjunction with the Treasury." It is important to stress again that the National Health Service Act is not an insurance scheme, and therefore is something radically different from the National Health Insurance Acts under which at present a large proportion of the population of this country is receiving medical care.

Some men in practice now are naturally worried about their financial position in the event of their refusal to serve under the Act in its present form. Young men wanting to enter into practice are also disturbed about the position. Mr. Bevan hoped that the young men would be on his side. Letters to this *Journal* suggest that he was being optimistic. The young men who qualified just before the war, and since, have had experience of what a Service is. We shall try to see how these two groups will be affected if Mr. Bevan's Act cannot come into operation on July 5.

The medical profession will be able to decide its future only if the majority of Noes is large enough. Our strength will lie in the size of the majority. If, for example, two-thirds or more of general practitioners stay outside the Service on July 5, what will be their position? This country is not over-doctored, and Mr. Bevan cannot run a Service with a third or less of general practitioners, even if they were evenly distributed throughout the country. He, or his successor, would have to reopen negotiations, and if as a result an acceptable Service were to be introduced the two-thirds who stayed out would have to receive compensation if—to contemplate what is unlikely—it was agreed that the custom of buying and selling of practices should cease. If the Minister were to refuse compensation

then those two-thirds would persist in their refusal to enter his Service. But it is probable that the two-thirds staying outside the Service would refuse to go in unless the custom of buying and selling of practices was retained. (In any case the profession will not agree to a "peace treaty" which does not include a victimization clause.) Whatever unsatisfactory features there may have been in this custom in the past, doctors are now fully alive to the fact that it is closely bound up with the preservation of the individual freedom of the general practitioner. The abolition of the ownership of goodwill is not essential to a comprehensive medical Service. Mr. Bevan thinks that for the State to own everything is good and that for the individual to own anything is bad—a not unusual thesis among the apostles of collectivism.

Mr. Bevan, whom *The Times* accuses of "crowning misjudgment" and of using "arguments that are both tortuous and pedantic," may hold fast to his appointed day in spite of overwhelming opposition. Few doctors are paid for all the work they do, but what some fear is a situation in which no payment of any kind would be forthcoming. If Mr. Bevan decided to ignore the wishes of the majority of doctors there would indeed be a crisis. The state of affairs would be confused for at least a few weeks. During that period doctors would have to charge their patients fees. If these patients were to say that they are paying 5s. to the National Insurance Fund the doctor would point out accurately and firmly that only 10d. of that was going to the payment of a small proportion of the total cost of the Health Service. And he would also point out that the medical profession was not being paid anything by the State and that the patient must put the blame at the door where it belongs—at the door of a Minister of Health who has refused to make doctors willing partners in his Health Service. We believe, too, that those who are fearful underestimate the loyalty of the individual patient to his own doctor. No working man—and this term includes at least 95% of the population—will grudge his doctor a fee which will be very small in relation to what he spends on beer and tobacco—fees to be paid over a period measured at the most in weeks. And if individual doctors do suffer temporary financial loss there are substantial funds to aid them—a fund which, incidentally, was helped along by a medical man who at a meeting last week handed the Secretary of the B.M.A. a cheque for £500 for this cause.

What are the present prospects for the young man wanting to enter general practice? At the moment some of them are finding difficulty in buying shares in partnerships. One reason for this is that elderly practitioners who would have retired are waiting until the issue of ownership of goodwill has been settled. If the profession should agree to the abolition of this custom these elderly practitioner are expecting to be compensated immediately after July 5. It will not be possible for them to receive this compensation money for at least two or three years after July 5. No compensation can be paid until all claims have been assessed, and the ambiguities of Section 35 are going to make it extremely difficult to arrive at this figure. In fact no one will know what the situation is until the matter has been thrashed out in the courts, because Mr. Bevan has

told the Negotiating Committee that this is something for the courts to decide.

The young man wanting to enter Mr. Bevan's Service as a principal on or just after July 5 would have to submit his name to the Local Executive Council of the area in which he wished to practise, and after the Executive Council has made its choice from a list of such names the successful applicant would have to receive the permission of the Medical Practices Committee in the Ministry of Health. In any case he will be able to work only in areas which are under-doctored, and these areas, we are told by Mr. Bevan, are at present few in number. Granted that a young man's application is successful, he will then have the privilege of "squatting" on a basic salary of £300 a year. He will have to buy or rent a house suitable for a doctor, and will have to buy his car, just as he does to-day. He will have no introduction to a practice and no list of patients with which he can make a substantial start in his new work. If he could practise from one of the infinitesimal number of Health Centres available he would still have to buy or rent his house to live in and in addition pay a rent for the use of accommodation in the Health Centre—accommodation in a Health Centre is not to be free of charge. And in a circular issued on Jan. 14 the Minister states that he proposes to set up a committee charged "with the task of gathering all useful existing information and formulating expert guidance on the best kinds and purposes of Health Centres at which development should aim." The Health Centre was the keystone of his new G.P. Service, and Mr. Bevan does not yet know what it should be like!

If a young man wants to enter general practice as an assistant to a doctor in the Public Service his choice of practitioners with whom he may wish to work will be severely limited. If, for example, a practitioner in the Public Service with a maximum number of patients on his list because of his success as a doctor wanted an assistant, he could not engage an assistant to meet the demands of the local community if the Executive Council and/or the Medical Practices Committee considered there were already enough doctors in that area. It will not matter to these administrative bodies whether the doctors in an area are good, bad, or indifferent. Their estimate of a position will, and must, be a purely quantitative one. In a quantitative scheme quality goes by the board.

There have been in the medical profession many critics of the custom of buying and selling practices. In the past some medical men have unfortunately fallen into the hands of unscrupulous moneylenders. Before the war the B.M.A., aware of this, made it possible for young men to borrow money through reputable sources and on reasonable terms. There is room for further exploration of the possibilities of making the loan of money for the purchase of a share in a practice much less burdensome than in the past. Doctors can put their collective heads together on this matter, as is indeed suggested by correspondents to this *Journal*. Ways and means should be sought for making things even easier for the young doctor wishing to buy a share in a practice, because what he gains through his ownership of goodwill is very considerable. First of all he secures an introduction to a practice. He is offered immediately something very much more substantial than

a basic salary of £300 a year. Exactly the same argument applies to assistants. A principal will take in an assistant because work is getting too much for him. He is saved the uncertainties and risks of "squatting" at £300 a year.

A man who buys a practice has a stake in the community in which he lives. He has got to make good and command the respect of the people among whom he works. A man in receipt of a salary from the State has no such stake. The struggle to make good is healthy. State subsidy of the mediocre is unhealthy. Doctors are now more sharply aware than ever before of the freedom from State interference which is provided by the ownership of practices. With the abolition of ownership, with the imposition of a universal basic salary, with the refusal of the right of appeal to the courts against the Minister's decision to sack a man in a Service open to the whole community, with the control of the distribution of doctors in the hands of a Ministry Committee, with the power in the hands of the Minister to change by Regulation a part-time into a whole-time State Service, doctors will cease to be members of an honourable profession and will become mere technicians employed by the State. Once this has happened Medicine will cease to attract into its ranks the type of man whose generation after generation has made Medicine and the medical profession what they are to-day.

Mr. Bevan and the propagandists who have supported him have spread many illusions about the supposed advantages of the present Act. We have already dealt with some of them in previous articles in this column. But one illusion still seems to persist, and that is that with the introduction of this Act medical men will work shorter hours on fixed rotas, and have longer and better holidays. Mr. Bevan cannot create more doctors, cannot build more hospitals, cannot build more health centres, cannot build more houses. He refers in his circular of Jan. 14 on Health Centres to "the sheer practical impossibility of a new building programme." The first effect of his Act will be vastly to increase the number of items of service. This is what happened when N.H.I. was introduced. A service apparently free to everyone will mean that many in it will have a tendency to use it irresponsibly.

The hypertrophy of bureaucracy is one of the social evils of our time. It may be a sign of our decline from greatness, and we may note that historians held it to be an important contribution in the decline of another great empire. We respect our Civil Servants as able and honourable men of an uncorrupt administration, but we believe nevertheless that the extension of their numbers and powers should be restricted if the freest play is to be given to those indispensable qualities of individuality and initiative which have made Medicine what it is to-day. We should take warning from Herbert Spencer, who sixty years ago wrote thus: "Judge what must under such conditions become the despotism of a graduated and centralized officialism, holding in its hands the resources of the community, and having behind it whatever amount of force it finds requisite to carry out its decrees and maintain what it calls order." Spencer saw a developed administrative organization leading to "a revival of despotism" and described this development in a chapter entitled "The Coming Slavery" in his book *Man versus the State*.

THE PRESS AND THE PROFESSION

Speaking at the opening of the East Glamorgan County Hospital on Saturday, Mr. Aneurin Bevan, the Minister of Health, gave this advice to doctors: "Do not allow your minds to be inflamed or your judgment to be distorted by slogans which are addressed to your emotions and not to your intelligence." This sound piece of advice is perhaps hardly necessary for members of a profession used to making a differential diagnosis. The doctor uses the methods of science, and the politician the technique of the hustings. At this moment the medical profession is being subjected to abuse, misrepresentation, and malicious innuendo from the highly emotional press which supports Mr. Bevan. This campaign was started by the *Tribune*, of which Mr. Bevan was a director and editor until he took office in the present Government in 1945. The *Tribune* suggested that "the B.M.A. may still try to fight the battle of the Tory Party against the development of a socialist service," and it went on to state: "Politically, the Minister's firmness has been most important. If he had been weak in face of this reactionary profession . . . it would have increased doubts as to the intention to carry out a socialist programme." The paper with which Mr. Bevan has been so closely associated started the campaign of abuse, and, be it noted, before the report of the so-called negotiations between Mr. Bevan and the Negotiating Committee was out. *John Bull*, published by Odhams Press, which, with the T.U.C., owns the *Daily Herald*, states that the plebiscite now to be held "does not sound like a genuine attempt to find out what doctors think about Aneurin Bevan's plans. It is more likely to be a time-wasting device thought up by the diehards at the B.M.A. headquarters." Mr. Michael Foot, who has just succeeded Mr. Jon Kimche as Editor of the *Tribune*, in a highly misleading article in the *Daily Herald* of Jan. 16 accuses the B.M.A. of attempting "to destroy a scheme devised by Parliament, even though the B.M.A. itself has never had any real alternative to offer." Mr. Foot begins his article thus: "Many miners object to certain sections of the Coal Nationalization Act; but they still dig coal." Has Mr. Foot never heard of coal strikes? And has he not beard of the recent action taken by the National Coal Board against a section of miners? He knows perfectly well that doctors never have struck and never will strike. Their sense of vocation is too strong, and the refusal to strike puts them in a weak position, and Mr. Bevan knows it. Miners, dockers, food-handlers and distributors can strike and endanger the life and health of the community, yet they become the white-headed boys of political propagandists like Mr. Foot who try to smear a great profession by hinting that they might adopt the methods of other sections of the community with a less educated sense of responsibility.

The *Daily Worker* naturally enough refers to medical men as "reactionary diehards," but also hits out at Mr. Bevan (Jan. 16) in this reference to the Ministry of Health circular on Health Centres: "Striking at the very basis of his own Health Service scheme, Mr. Bevan yesterday announced the postponement for a long time, at least, of any construction of health centres." The *Daily Mirror* observes that after the Bolshevik revolution Russian doctors

were opposed to National Health Insurance, and adds, presumably with approval, this: "They got the usual Russian short shrift. . . ." The *Mirror* draws attention to our responsibility in resisting Mr. Bevan's Act when it states: "It's quite certain that if the British plan works it will be copied throughout the Empire and throughout Europe."

The *Sunday Pictorial*, weekly sister to the *Mirror*, calls Mr. Bevan's scheme "the State Medical Service," and observes that "the Health Act went through Parliament by the will of the people. They [the doctors] assume grave responsibility in opposing that will." This is the present propaganda line of Mr. Bevan's supporters, and was most effectively answered last Sunday by Dr. H. Guy Dain, the Chairman of Council. "Parliament," Dr. Dain said, "has imposed no obligation whatever on doctors to join the Service. On the contrary, Parliament has expressly given the profession the right to enter or to stay out as it chooses. Mr. Bevan himself has explicitly admitted that this is so. He has also admitted that doctors, like other workers, have the right to make up their minds collectively, as well as individually." It is important that medical men should keep this fact firmly in mind—namely, that individual and collective opposition to serve under Mr. Bevan's scheme is an action which Mr. Bevan holds to be one to which we have a right. The issue is simply whether medical men are willing to take service under the National Health Service Act in its present form if the plebiscite results in a majority large enough to justify collective opposition. Those who are trying to frighten doctors with the bogey of opposing Parliament should reflect upon Mr. Bevan's own observation and also upon an observation made by a philosopher whose views were endorsed in a preface to a reprint written by that stalwart of the Labour Party, the late Lord Snell. Herbert Spencer¹ wrote:

"The great political superstition of the past was the divine right of kings. The great political superstition of the present is the divine right of Parliament. The oil of anointing seems unaware to have dripped from the head of the one to the heads of the many and given sacredness to them also and to their decrees."

There is nothing sacred about Mr. Bevan's Act. What is sacred is the freedom of the medical man to decide not to enter a service which threatens his freedom and his responsibility towards his patients.

Large sections of the Press, and in particular the small provincial paper which plays such an important part in forming public opinion, show a sympathetic appreciation of "the doctors' case." We are here more concerned with those who fail to see, or wilfully ignore, what is the fundamental problem the medical profession is faced with. Ranging itself on the side of those papers referred to we find *The Times*, which pursues its unrelenting course of opposition to the British Medical Association. In a leading article of Jan. 8 *The Times* momentarily wavered from its opposition when it stated: "Mr. Bevan has not convincingly explained why the basic salary should not be confined to special cases, and if a majority of doctors now votes against this it would be wise to abandon its general application without hesitation." But in a leading article six days later

¹ *Man versus the State*. By Herbert Spencer. (With an introduction by Lord Snell, C.B.E., LL.D.). The Thinker's Library. London: Watts & Co., 5-6, Johnson's Court, Fleet Street, E.C.4.

(Jan. 14) *The Times* repented of its moderation and stated: "Nor, again, can the ordinary citizen see why the B.M.A. should . . . resist the introduction of a small basic salary for all practitioners." *The Times* completely ignores the basis of the B.M.A.'s opposition, which is that the Act in its present form leads to a whole-time State Medical Service—leads to the nationalization of Medicine. When all services and industries in the State have been nationalized *The Times* and other independent newspapers may see an attempt to nationalize the Press. That it can ignore the implications of the present attempt to nationalize a free and independent profession is surprising. What is perhaps more surprising is to find *The Times* making a misstatement of fact. "The B.M.A.," it states, "has never had a workable scheme of its own." This is not true. Between the two wars the B.M.A. was working on plans for a general medical service for the nation and the last statement of its views on this was published in 1938—a scheme which advocated the inclusion of dependants in the National Health Insurance scheme, the inclusion in it of all persons of like economic status to those to whom the scheme was available, and the extension of the scheme to include consultant and auxiliary services. This was a workable scheme based upon an existing scheme which, whatever its defects, commended itself to the public and the profession. *The Times* writes: "The dispute has been allowed to drag on as though it were a private wrangle of no public importance between the Minister of Health and a score of elderly doctors. It is high time that the Government and public opinion intervened to prevent a conflict which would be as exasperating as it would be futile." Lord Horder dealt effectively with the slighting reference to elderly doctors when he pointed out² that the average age of the 34 members of the Negotiating Committee was 59, and that of the Cabinet 58. He added:

"But in this matter of consultation the Minister has done less than justice to the public, the doctors, and himself. He burked discussion before the Act was put upon the Statute-book, and now it is there he tells us that Parliament has spoken and he cannot reopen matters which he knows full well have always been in dispute. He allowed these matters to be discussed with his subordinates for 12 months and then himself disposed of all of them in two sessions of two hours each. Frank consideration of amending legislation to the Act as it now stands was promised. Such consideration has not been vouchsafed."

The Times asks whether "the B.M.A. questionnaire will be so framed as to indicate whether the doctors' particular objections can be remedied without destroying the basis of the scheme." And it admits that the "doctors certainly have genuine grievances. . . ." Mr. Bevan's comprehensive Health Service can be operated willingly by medical men if he concedes on matters not essential to the working of his Act. These include: the right of appeal to the Courts against the Minister's decision to remove a man from the Service; the abolition of the basic salary except in certain circumstances; payment by a fixed capitation fee; the machinery for directing ("negatively") doctors; and the right of doctors to continue to own the goodwill of practices.

THE MINISTER CLARIFIES

In an attempt to clarify some points in the present dispute between the Minister of Health and the medical profession, the *Lancet* put nine questions to the Minister. By the courtesy of the Editor of the *Lancet* we are able to publish in this week's *Journal* these nine questions and Mr. Bevan's replies to them. There are three questions on remuneration; three on the right of appeal in the Tribunal; a question on Section 35 of the Act in relation to the legal position of partnerships; and two questions on the possible postponement of the appointed day.

Mr. Bevan persists in his refusal to give the medical man the right to appeal to the courts against a decision to remove him from a service open to every member of the public. That there can be no real constitutional or administrative obstacle in the way of granting this appeal is clear from the fact that it is included in the National Health Service Bill for Northern Ireland. Mr. Bevan repeats the observations on this matter he has already made to the Negotiating Committee: all the doctor can do is to challenge the legality of procedure, not the decision to dismiss; the Minister is the employer and insists on the right to sack his employees. Mr. Bevan says that "'basic salary' is perhaps a misnomer," and states that the proposed fixed element of £300 "does not in any way affect the prospects of a fully salaried system; this could be brought about with or without this £300 element." He observes that a full-time salaried Service has been possible under existing legislation for some 36 years. This, of course, refers to remuneration under the National Health Insurance scheme. The National Health Service Act is open to all members of the community and has been framed and is being brought into operation by a Government which is pledged to introduce a whole-time salaried State Medical Service. The first of the reasons Mr. Bevan gives for "a universal basic salary" is "that it enables beginners to live while they attract patients." The second is that "it affords a convenient fixed peg on which to hang additional payments," and the third "that it reduces the temptation to build up excessively long patient lists." These read like excuses rather than reasons.

On Section 35 the Minister has retreated from the position he took up when he met the Negotiating Committee on Dec. 2 and 3. He states that, "anxious to clarify the position . . . he . . . proposes to obtain a collective legal opinion of highest standing by appointing straightway a committee of legal experts to say whether or not the partner in an existing partnership is fully and adequately protected." He goes on to say that he will proceed to seek amendment of the Act if on the report of this legal committee "there is evidence that existing partnerships are unfairly prejudiced by the Act." This legal committee has to be set up. It will have to make its considered report. If its report provides evidence of prejudice to existing partnerships Mr. Bevan will seek to amend the Act. Until all this has been done no medical man in partnership will know where or how he stands—probably not until the eve of the appointed day. Mr. Bevan has just been compelled to postpone indefinitely the building of health centres which were the key-point of his general practitioner service.

and now is forced to admit by the evidence of the Negotiating Committee that he does not know how to interpret a section of the Act related to partnerships and related hereby to the assessment of compensation. Once again Mr. Bevan flouts the Negotiating Committee by making his new proposal not to it but to a medical weekly owned by a publishing firm.

Mr. Bevan states that the National Health Insurance Acts were repealed not by the National Health Service Act but by the National Insurance Act which comes into operation on July 5. The medical profession is expected to enter the Service without being in full possession of all the facts—for example, the remuneration of consultants will probably still be under discussion in June, the legal position of Section 35 has now to be clarified and an amendment possibly introduced, and Mr. Bevan is still unable to make an exact comparison between his proposals for remuneration and the proposals of the Spens Committee, which he has accepted and which have been in his hands for months. If there is administrative difficulty over the postponing of the appointed day it is the job of the administrator to get over it. In reply to the *Lancet's* question whether further postponement of part of the Service will be contrary to the public interest Mr. Bevan replies that for his part "the Minister will give them the Service on July 5." It is the medical men of this country and not the Minister who will be working in the Health Service. Mr. Bevan has had the grace to reconsider one section of the Act. Encouraged by this we must persist in asking him to reconsider other sections of the Act if the comprehensive medical service wished for is to be introduced on July 5.

RECENT OUTBREAKS OF SMALLPOX

The diagnosis of typical smallpox presents few difficulties. Unhappily, when it occurs in individuals who possess some basal immunity the clinical picture is more confusing and may confound even the experts (and they may nod in good company, for even Ricketts himself is said to have misdiagnosed a case). But, although the illness may be mild and indefinite in a host who is partially immune, the virus itself loses none of its virulence and may still cause severe disease in susceptible contacts. The results of a missed diagnosis may thus be calamitous, and elsewhere in this issue Simpson Smith describes the events which followed a "confident diagnosis of chicken-pox" in a soldier returned from India. An epidemic of smallpox ensued which smouldered for four months. There were thirty cases in all, of which half were severe and six died.

Although there have been no spectacular epidemics in this country since the passing of the Vaccination Acts, we all need constant reminders that smallpox is never absent for long from these islands. In the period 1921–35 inclusive there were 81,556 cases, with 266 deaths in England and Wales.¹ Most of these cases were of a mild type, as is evident from the low mortality. During 1936 only 12 cases were notified—the infection having been introduced from abroad—and Butterworth² was induced to prophesy: "Few medical men are likely to see variola major in this country, for it is now very rare."

On the outbreak of war the possibility of infection entering this country from the Eastern Mediterranean and other endemic areas led to a tightening of the usual measures of control at ports and airfields. Despite these, however, an outbreak of smallpox occurred in Glasgow in June and July of 1942, a full account of which was given in this *Journal* by Sir Alexander Macgregor.³ There were 36 cases, with eight deaths, the first cases being members of the crew and passengers of a ship which had sailed from Bombay. Mass vaccination, which formed part of the administrative procedure to combat the disease in Glasgow, did not materially interfere with the normal work in the docks.⁴ The question of the value of this method of control in stopping the epidemic was discussed in our columns at that time.⁵ Later in the same year similar outbreaks occurred in Fife and Edinburgh.

The next outbreak to attract attention began in a Middlesex hospital.⁶ Here the original case was a soldier who had arrived in a convoy from Gibraltar and who had been admitted direct to the hospital on account of an anxiety state.⁷ There followed ten cases of variola major, three of them fatal. During 1946 Asiatic smallpox was introduced into England and Wales on 15 separate occasions. Fortunately vaccination and surveillance of contacts brought the disease rapidly under control in each case, and only 40 persons became infected. Then, after an interval of seven months, the disease reappeared in the middle of February, 1947, and cases were seen at Grimsby, Stepney, Scunthorpe, Doncaster, and in Staffordshire.⁸

Meanwhile the outbreaks among British soldiers in the Middle East had caused van Rooyen and Illingworth⁹ to explore methods of rapid diagnosis. They found that the direct examination of carefully prepared smears from early lesions was useful in differentiating chicken-pox and smallpox owing to the larger size of the elementary bodies in the latter disease. Downie¹⁰ has more recently reviewed the laboratory methods available for the diagnosis of smallpox. He is doubtful of the value of direct examination, for a negative result does not exclude smallpox, and considers that the two most reliable methods are the cultivation of the virus from early lesions on the developing egg, and the complement-fixation test, using as antigen material from at least six vesicles or a similar number of scabs. The latter test gave positive results in all of 27 recent cases,¹¹ and has the great advantage that a definite report can be given within 24 hours, whereas egg culture takes at least three days.

So long as British troops remain in the Middle East their repatriation by aeroplane or ship will entail a risk of localized outbreaks of smallpox in this country. In one month last year cases were landed from the *Empress of Australia*, the *Duchess of Richmond*, and the *Orontes*.¹²

¹³ Stallybrass, C. O., *Publ. Hlth.*, 1947, Jan., 82.

It is true that the risk to the civilian population is not great, but as movement becomes freer and air travel develops, as it is bound to do, the comparative freedom from the disease which we enjoyed immediately before the war is unlikely to continue. By the National Health Service Act, 1946, all the Vaccination Acts are repealed and vaccination is put on the same voluntary basis as diphtheria immunization. For a country which depends as much now as it has in the past on its maritime associations this bold step is an act of faith which will need to be accompanied by suitable campaigns to educate the public. It will be unsatisfactory to rely on vaccination only after the appearance of a case, for it may be noted that Simpson Smith found that vaccination is no certain prophylactic after contact has occurred. Stallybrass¹³ made the same observation following the onset of smallpox in two patients in Liverpool, both of whom died.

Recent experience may be summarized briefly. First, there is no absolute clinical diagnostic criterion; even the distribution of the rash may be misleading in greatly modified cases. Secondly, the appearance of even a few papules after a constitutional upset (which will usually be regarded as "flu") should always arouse suspicion. Thirdly, the diagnosis of chicken-pox in an adult should be made with misgivings, especially if there is a history of recent residence abroad. Finally, laboratory tests now give valuable and accurate information, and there should be no hesitation in using them even if it is only to confirm an apparently obvious diagnosis.

CARE OF CHILDREN

The National Assistance Bill will bring to an end the existing Poor Law and make further provision for the welfare of disabled, sick, aged, and other persons.¹ In this Bill the effect of the recent awakening of public interest in the care of the aged, as shown among other things by the report of a special committee of the British Medical Association,² can be traced. The Children Bill, the text of which was published on Jan. 16, is a further instalment of the new legislation which will come into operation when the Poor Law ends, and it reflects faithfully the recommendations of the Curtis Committee and the Clyde Committee. Miss Myra Curtis, C.B.E., presided over the Care of Children Committee which was set up in March, 1945, "to inquire into existing methods of providing for children who, through loss of parents or from any cause whatever, are deprived of a normal home life with their own parents or relatives."

The Curtis Report³ attracted a great deal of attention when it was published in September, 1946, and so did the less familiar Clyde Report of the Scottish Committee on Homeless Children.⁴ The Children Bill gives effect to most of the recommendations of the Curtis Committee, following the main lines of its detailed proposals on administration and also, wherever possible, giving preference to personal relations rather than official intervention. The White Paper⁵ summarizing the main provisions of the Bill points out that it will place a duty on the councils of counties and county boroughs in England and Wales and of counties and large

burghs in Scotland to receive into their care in the interests of the welfare of the child any boy or girl under seventeen who has no parents or guardians or who has been abandoned or lost or whose parents or guardians are prevented by incapacity or any other circumstances from providing proper accommodation, maintenance, and upbringing. This duty will rest on the local authority in whose area the child is, irrespective of where he or she is ordinarily resident. An important point is that the Bill does not authorize a local authority to keep a child if any parent or guardian desires to take over this responsibility. Local authorities will be able "to assume by resolution" parental rights. But such a resolution will lapse if any parent or guardian whose rights are affected lodges an objection within one month. It will then be open to the local authority to apply to the courts for an order that it should remain in force. The burden of proof will rest upon the local authority, which must satisfy a court that its intervention is necessary in the interests of the child.

In the cases which the Curtis Committee studied, however, and with which the Bill is primarily concerned there is no question of such a dispute. The child is alone and uncared for and the Bill places squarely upon the shoulders of the local authority the duty of taking charge of him. For many years local authorities have been acting voluntarily as "fit persons" to take charge of children reported to be "in need of care or protection." This voluntarily assumed responsibility will now become a duty. Normally the local authority will discharge this responsibility by boarding the child out with foster parents or, if this is not possible, in some form of home or hostel maintained either by voluntary bodies or by the local authority itself for this purpose.

The whole plan will be under the supervision of the Home Office, and the Secretary of State is empowered to make Regulations for maintaining the standard of institutions accepting these homeless children. Local authorities are also to set up Children's Committees under which a children's officer will work. In the great majority of cases this officer will be a woman and, according to *The Times*,⁶ "it will be her duty to be the channel for all the forces of public benevolence that flow from legislative and official sources, but to pass them on transformed into personal understanding and solicitude."

The responsibility placed on the local authority under the Bill will end if the child comes under the control of any person or authority under the provisions of the Mental Deficiency or the Lunacy and Mental Treatment Acts. In making Regulations governing the conduct of voluntary homes the Secretary of State may include provisions relating to accommodation and equipment, medical arrangements for protecting the health of the children, and facilities for religious instruction. There will be set up an Advisory Council on Child Care to advise the Secretary of State on matters connected with the discharge of his functions under this Bill once it becomes an Act and under the Children and Young Persons Act of 1933. There will be a separate Advisory Council for Scotland. It is estimated that the Children Bill will affect the upbringing of some 125,000 children in England and Wales and about 13,500 in Scotland.

Prof. G. S. Wilson, M.D., F.R.C.P., will deliver the Milroy Lectures before the Royal College of Physicians of London (Pall Mall East, S.W.) on Tuesday and Thursday, February 10 and 12, at 5 p.m. His subject is "The Public Health Laboratory Service."

THE MINISTER OF HEALTH ANSWERS THE "LANCET"

The LANCET this week publishes the Minister of Health's replies to a series of questions addressed to him by the Editor. The following are the questions and answers, which we reproduce by the courtesy of the Editor of the LANCET.

1. *Will the Minister further explain the purposes of the basic salary?*

"Basic salary" is perhaps a misnomer. It suggests a salaried State medical service. But the Minister, in the debate on the National Health Service Act on Nov. 4, 1946, said:

"Some doctors have expressed the fear that this is merely the beginning of a full-time salaried service. I cannot read into the mind of any future Minister or prophesy what may be done by future Governments, but that is not our intention. Our intention is that the main source of a doctor's remuneration shall be by capitation."

This statement is reflected in the remuneration now proposed. It should be remembered that the new Act gives no more power to impose a full-time salaried service than does the existing law. A full-time salaried service has been possible under existing legislation for some 36 years—but doctors have not apparently feared it. It should also be remembered that the proposed £300 "fixed" element in payment does not in any way affect the prospects of a full salary system; that could be brought about with or without this £300 element, which makes no difference.

The values of the "fixed" payment of £300 in the total remuneration are (a) that it enables beginners to live while they attract patients, (b) that it affords a convenient fixed peg on which to hang additional payments (e.g., for sparsely populated areas) without the administrative complications of a varying capitation rate, and (c) that it reduces the temptation to try to build up excessively long patient lists.

2. *Could not the purposes of the basic salary be fulfilled by an alternative capitation fee (if necessary on a sliding scale) offered to those practitioners who opt for it?*

A system of alternative capitation fees would involve substantial administrative difficulties, particularly if "collective responsibility" and a pooled capitation fund are—as they are—to be accepted. Nor would the purposes above be fulfilled. No good case has been made out for it so far.

3. *Will the Minister amplify his statement that the doctor retains "his ordinary legal right to go to the Courts on grounds of unlawful action by the Minister or others" and indicate how far this will give doctors the assurance of protection, where necessary, by the Courts?*

There has been general misunderstanding on this. The business of the Courts is to decide whether a termination of any form of employment is lawful or unlawful. On this the doctor, like everyone else, can still go to the Courts. Any person affected by a decision of the Minister can go to the High Court on the question whether the Minister has, or has not, acted lawfully. Nobody, in any other profession or vocation, has the right to ask a Court to reverse a perfectly lawful decision to terminate an engagement. No such right—indeed, no independent Tribunal—has existed under National Health Insurance in the last 36 years. The Minister could have carried on the present system of that scheme, but—on the doctors' behalf—he provided for the decision to be taken by a separate Tribunal and not by him. The appeal to him is only an appeal to keep the doctor in the Service in spite of the Tribunal. There is no power in him to alter a decision of the Tribunal favourable to the doctors.

Let it be clear what the doctors' protection is. First, the Minister himself cannot ever remove any doctor's name from the list. Locally an Executive Council comes to the conclusion that the continued inclusion of a certain doctor in the lists would prejudice the efficiency of the Service. That Council is itself half professional and has seven doctors on it. That Council, nevertheless, cannot remove the doctor's name from the list; it can only refer the case to a special Tribunal of one

doctor, one lawyer (appointed by the Lord Chancellor, not the Minister), and one layman. That Tribunal can decide in favour of the doctor—in which event nobody at all can overrule it. Or it can decide against him—in which case he has the further recourse to the Minister, mentioned in the last paragraph. The Minister can uphold the Tribunal's decision, or reverse it in the doctor's favour—nothing else. There are many who think it is, if anything, the public rather than the doctor who might claim to be more protected.

4. *For the practitioner, what advantages are there in having his case heard by the Tribunal rather than a Court of Law? Could not the advantages of the two forms of hearing be combined by allowing appeal from the Tribunal to a Court?*

Part of the answer is given above. The Courts' proper function is to decide whether what is done is lawfully done. That remains. Under the existing National Health Insurance it is the Minister who decides these cases. Under the proposed new Service an independent Tribunal is set up to decide it, and unless the doctor wishes otherwise the proceedings are private. The Minister can reverse that Tribunal's decision only in the doctor's favour.

5. *It has been suggested that the chairman of the Tribunal, nominated by the Lord Chancellor, should be a judge. Would the Minister consider the appointment of judges as chairmen of Tribunals?*

As the Act stands, this is not possible. The Minister sees no good reason to amend it in this respect. A judge, so appointed, would not be acting as a judge, and the difference is more apparent than real. Nor is it easy to find judges available to give the time to this. What matters is that the chairman should be a lawyer of acknowledged standing, and this it is the intention to secure.

6. *Could not steps be taken, in advance, to clarify the legal position of partnerships after the appointed day?*

The Minister is in complete sympathy with the doctor in partnership who feels that his position under his partnership agreement is uncertain. He is advised that legally the situation is all right and the partner protected. The B.M.A. is advised otherwise. The Minister is anxious to clarify the position, but—on the present legal opinions—it is not easy to do so. He therefore proposes to obtain a collective legal opinion of high standing by appointing, straightway, a committee of legal experts to say whether or not the partner in an existing partnership is fully and adequately protected. He would like the profession's co-operation in the selection of that committee. He will consider its report, and, if there is evidence that existing partnerships are unfairly prejudiced by the Act, he will proceed at once to seek an amendment of it.

7. *Will the Minister comment on the statement that in the middle and higher ranges his proposals for remuneration do not tally with the recommendations of the Spens Committee?*

His intention has certainly been that they should tally. But, at this stage, no exact comparison has been possible. So far, he has published only the main and fundamental remuneration of the general practitioner. Account has still to be taken of additional factors which have not yet been settled—such as additional payments for maternity services, grants for training assistants, income derived from the employment of assistants in the bigger practices, the value of the Exchequer contributions to superannuation (which the Spens Committee said must be taken into account and which will amount to 8% of the net income) and of the right to a widow's pension.

8. *If the "appointed day" for the operation of the National Health Service Act were again postponed, would National Health Insurance continue until that day?*

No. The National Health Insurance Acts are repealed, not by the National Health Service Act, but by the National Insurance Act, which operates from July 5.

9. *Will the Minister explain why in his opinion further postponement of the introduction of the Service, or of the general practitioner part of it, would be contrary to the public interest?*

Since 1942, under different Governments, the conception of a national and comprehensive health service has been actively

pursued. The present Government put it into effect, and Parliament endorsed it, in 1946. It is time that the people had it. The old system is partial and, from the national point of view, not effective enough. The country can have—and should have—the complete cover for health which they deserve. Parliament has decided how they can best have it. It is the Minister's duty to carry out that decision, and he is doing so. He has preserved all the confidential and personal relationships of doctor and patient which are essential to any health care, the freedom of choice of doctor and freedom to change. He has tried to remove the financial worry of health care by a system of pooling costs and drawing benefit when the need arises. To withdraw the general practitioner service would be to remove from the new health "cover" the very first line of medical consultation. Why should the people wait longer? For his part, the Minister will give them the Service on July 5.

THE PLEBISCITE FORM

On Jan. 31 the British Medical Association is sending the plebiscite form to all medical practitioners in England, Scotland, and Wales, those in the Services wherever they are, and those on the Temporary Register. The purpose of the plebiscite is, first, to ascertain the views of the profession on the National Health Service Act in its present form, and, secondly, to decide the question of "service or no service." To this end three questions will be asked and the practitioner gives his answer by marking an X against the affirmative or negative form of the question. They are as follows:

- A { *I approve of the N.H.S. Act, 1946, in its present form.*
I disapprove of the N.H.S. Act, 1946, in its present form.
- B { *I am in favour of accepting service under the Act in its present form.*
I am not in favour of accepting service under the Act in its present form.
- C { *I agree to abide by the decision of the majority and undertake not to enter the Service if the answers to Part B reveal a majority against undertaking service, as defined in para. 4 above [of the plebiscite form], and if so advised by the British Medical Association.*
I do not agree to abide by the decision of the majority if it is against accepting service as defined in para. 4 above. [See third paragraph below]

All members of the profession will be asked to complete question A whether they are in practice or retired. Questions B and C should be completed by the following groups of practitioners: consultants or specialists not holding whole-time salaried posts; consultants or specialists holding whole-time salaried posts; general practitioners who are principals; general practitioners who are assistants; and whole-time voluntary staff.

The last category excludes those practitioners of specialist status who appear in the first two categories listed. It includes those practitioners holding B1, B2, and A appointments and Class I and Class III appointments under the Government postgraduate scheme for ex-Service men. It will be seen, therefore, that house-officers, registrars, resident officers, chief assistants, and members of professorial units at voluntary hospitals all vote on these questions B and C.

The advice that the Council of the British Medical Association will give to the profession depends on the result of this plebiscite. If the total replies to question B show a majority against accepting service under the Act, and this majority includes approximately 13,000 general practitioners (out of a present total of about 20,500 general practitioners), the Association will advise the profession not to enter any contract under the Act in its present form but to continue their services to patients, or other professional work. If these majorities are not attained, those practitioners who undertake not to enter the Service (in answer to question C) will be released from their obligations. Needless to say, how individuals vote will not at any time be disclosed.

In order to clarify the replies 19 categories will be printed on the plebiscite form and the medical practitioner asked to

assign himself to one of them. They are as follows: (1a) Consultant or specialist not holding whole-time salaried post (1b) Consultant or specialist holding whole-time salaried post (2) General practitioner—principal; (3) General practitioner—assistant; (4) Whole-time voluntary hospital; (5) Whole-time local authority general hospital; (6) Whole-time local authority special hospital; (7) Whole-time public health service; (8) Whole-time Government service; (9) Whole-time teacher; (10) Whole-time research; (11) Other whole-time non-Government post; (12) Medically qualified dental surgeon; (13) Retired; (14) Unclassified; (15) Service permanent commission; (16) Services, temporary commission, specialist; (17) Services, temporary commission, grade specialist; (18) Services, temporary commission, general duty officer.

It is particularly asked that every medical man should fill in this important document and return it not later than Feb. 1 (or as soon as possible in the case of practitioners overseas), to the Secretary of the British Medical Association, B.M.A. House, Tavistock Square, London, W.C.1.

THE MENTAL HEALTH SERVICE

WIDER RESPONSIBILITIES OF LOCAL AUTHORITIES

A conference arranged by the National Association for Mental Health was held in London on Jan. 15 and 16, and attended by delegates from a large number of local authorities and voluntary organizations. The subjects of discussion at the two sessions were the rehabilitation of persons who have suffered from nervous or mental disorder, methods of handling "difficult" children, the responsibilities of local authorities in relation to mental health under the National Health Service Act, 1946, and, finally, education for mental health as a national and international responsibility.

The conference was opened by the Rt. Hon. R. A. Butler M.P., who enlarged upon the opportunity given to the National Association (which now incorporates the Central Association for Mental Welfare, the Child Guidance Council, and the National Association for Mental Hygiene) to play a leading part in developing an effective mental health service for the nation thanks to the provisions of the Education Act, 1944, and the National Health Service Act, 1946. Mr. L. J. Edwards M.P., Parliamentary Secretary, Ministry of Health, reminded the Conference that however complete the administrative arrangements under the Health Service Act might be, the success of the new health service would depend upon the quality of the work done by those engaged in it, whether as doctors and health workers or as representatives on local health committees. He urged that particular attention should be paid by local authorities to their after-care organization upon which the restoration to normal health of patients discharged from hospital would depend.

Readaptation after Mental Illness

Dr. G. R. Hargreaves, principal medical officer, Lever Bros. and Unilever, Ltd., said that various estimates had been made of the prevalence of the neuroses, many of them wide of the mark. Perhaps the closest index was afforded by an extensive inquiry which Dr. Russell Fraser had conducted for the Medical Research Council. He had shown that absence from work on account of neurosis was responsible for the loss of 1% of men's time in industry, equivalent to between one-third and one-quarter of all time lost through sickness, and that women lost twice as much time as men. The incapacity caused by neurosis was probably greater than that caused by colds and influenza.

To meet this problem the present facilities for out-patient consultation and psychological treatment were not adequate either in extent or quality, and in-patient facilities, whether in special centres or in general hospitals, were also inadequate. Mental hospitals designed for the care and custody of cases of psychotic illness, with few exceptions, were unable to provide adequate in-patient treatment for neurosis. The E.M.S. and Service neurosis centres had left some trace, notably in the Roffey Park rehabilitation centre and the Princess Elizabeth industrial rehabilitation centre of the L.C.C., but far more in-patient centres of this type were needed.

Most discussion on rehabilitation, said Dr. Hargreaves, was based on the assumption that the chief problem was to get an thopaedic case back to light work, but every works manager could say that he had no problem in the rehabilitation of such cases compared with the resettlement of neuroses and psychosomatic cases, such as patients with duodenal ulcer, in general industry. An after-care scheme, such as that which the National Association for Mental Health set up during the war for men discharged from the Services on psychiatric grounds, was badly needed for the civilian psychological patient in peacetime to enable him to get resettled in home and work.

The Ministry of Health, as was apparent from the decision to appoint regional psychiatrists, was aware of the social and industrial importance of psychiatric illness. Close collaboration between the remedial activities of the Regional Hospital Boards and the preventive activities of the local authorities would be needed if the resettlement of the neurotic patient in industry was to be achieved.

Resettlement in Industry

Dr. Donald Stewart, medical adviser to the Austin Motor Company, said that neurosis accounted for well over 90% of psychiatric cases, and was probably a factor in 20 to 30% of sickness. He divided psychiatric cases for practical purposes to three categories: (1) psychiatric cases among the unemployed, including psychopathic personalities, cases with a basis in mental defect, and those who had suffered from psychotic illness; (2) psychiatric cases registered as such with the Ministry of Labour, and in employment, but with a disability which from time to time might render them unfit for work; (3) psychiatric cases not on any register, and largely in employment, many of them detectable in industry by the medical officer, some showing anxiety states or depression superimposed on a prolonged organic disability such as tuberculosis or rheumatoid arthritis.

Under the National Health Service Act the treatment of psychiatric casualties in hospitals, clinics, and health centres was apparently to be put on a more rational foundation. It might therefore be that the new health service would pay attention to the adequacy of methods of recognition, treatment, and prevention. But in order to do this adequately its link with industry must be strengthened, particularly in the field of resettlement. Dr. Stewart described the various rehabilitation facilities available, and continued:

"Wide opportunity for modern medicine to take an active part in post-hospital rehabilitation is now offered. The doctor who has insight into and understanding of the psychological reactions of the worker, of his social customs, and of how his present outlook can be determined by fear of unemployment and the feeling of insecurity in his job, can do much to bring about changes in attitude. What industry and those Government departments more intimately concerned with resettlement increasingly require is advice from the doctor closely informed on both industrial and psychiatric matters, and who talks the common language. A further vista in education, both of doctors and laymen, is thus opened out. Training for this specific task now becomes of much significance."

Training, however, depended on research. Some proposals for investigation in this field were at present under consideration. One of the most important was the investigation of placement in jobs by studying on the one hand the physical and psychological demands of the different jobs and, on the other, the corresponding capacities of the individual. In the psychological approach such factors as incentives, fatigue, monotony, and working environment needed careful consideration.

Psychiatric After-care

An account of the working of the National Association's after-care scheme for psychiatric casualties, already referred to by Dr. Hargreaves, was given by Dr. Kenneth Soddy, medical director of the National Association. This scheme, which started in 1942, and in 1946 was thrown open to others besides ex-Service people, had dealt with between 13,000 and 14,000 men and women, and the present active case-load was over 4,000. It looked as if two and a half years was the average time for patients to remain in touch with the scheme. About one-third of the patients came into the scheme suffering from a psychotic illness, while nearly one-half were of the neurotic type. About one-third were referred by hospitals or

doctors, and rather fewer by employment exchanges. Only about a quarter of the patients could name a doctor as being their "own doctor," so that the scheme was evidently breaking new ground. About 9% of the patients at any one time were receiving treatment in mental hospitals or neurosis centres, and 7% in psychiatric out-patient clinics. These low figures might be due in part to the patients' lack of co-operation or lack of confidence in psychiatric treatment, but they were also an indication of the inadequacy of psychiatric clinical facilities and of the dearth of trained and experienced doctors. Some 60% of the patients were gainfully employed, and of those in work 63% had found employment by their own efforts, aided in some cases by a social worker. The hard core of unplaceables accounted for about 8% of the case load.

Psychiatric community care, said Dr. Soddy, cut across established divisions of work. It was not confined to medical treatment, nor to social welfare, nor to the promotion of industrial efficiency. Under the new Act it stood in danger of dismemberment between the Regional Hospital Boards and the local health authorities. The arbitrary division between medical treatment and social care had its administrative convenience, but it embarrassed the psychiatric therapist. Purely local schemes might suffer from patchiness and standards vary from area to area. His hope was that the larger health authorities might carry on and expand the National Association's pioneer work in community care and that the smaller authorities might perhaps make arrangements with the National Association to work on a co-operative basis over groups of areas.

New Powers and Duties of Health Authorities

A comprehensive survey of the new powers and duties of local authorities in respect of mental health under the National Health Service Act was given by Dr. Doris M. Odium, a vice-president of the National Association. She said that from the meagre reference to mental health in the Act it might be supposed that only a limited service was expected from local authorities, but a more careful study made it clear that the door was now wide open for a much more complete and satisfactory mental health service than had been possible in the past.

The Local Health Committees to be set up under the Act were empowered to refer all mental health questions to Mental Health Subcommittees, to which co-opted members could be added, thereby bringing in persons with special knowledge in the mental health field. The Minister had suggested to local health authorities that they should appoint a "medical officer of mental health," whole- or part-time, who would be a senior psychiatrist, or at least of consultant status.

Apart from the duties of ascertainment under the older Acts dealing with the mentally disordered and the mentally defective, and the taking of initial steps towards institutional care or other supervision as the case might be, local authorities had the power—and if the Minister so directed the duty—to make arrangements for the prevention of illness and the care and after-care of persons suffering from mental illness or defect. The Ministry had informed them that this provision was to be interpreted in a far wider sense than the categories coming under the older Acts, and that it included uncerifiable psychotics and mental defectives, neurotics, psychopaths, and subnormals, in fact all who were seriously handicapped by mental disease, disorder, or disability.

The care and after-care of all sorts and conditions of mentally ill people opened up an immense field. Dr. Odium said that she could not pretend that in these austere times it would be possible to carry out all these functions immediately, but it was to be hoped that every local authority would prepare a comprehensive scheme, and in the meantime, with the help of voluntary organizations, would cover as much of the ground as was possible. She indicated ways in which the psychiatric social worker could be of great assistance at the critical time of a patient's readjustment to domestic and working conditions.

Of preventive measures one of the most important was health education. Superstitious and morbid ideas still surrounded mental illness, and some patients were treated with real mental cruelty by their families, which militated against their recovery at the most curable stage of their illness. A programme of health education was necessary to avoid such an unhappy situation. The problems presented by the senile, the

subnormal, the unstable, the epileptic, and the psychopathic personality were widely different, but all these classes were capable of being helped to a greater or less extent by trained social workers. She also stressed the need for co-operation between the Mental Health Subcommittee and the Education Committee on the social care of school-children who were emotionally unstable or maladjusted.

Local Authority Opinion

Many delegates from local authorities briefly addressed the Conference on this subject. Alderman G. R. Spruit (Hull) spoke of the lack of co-ordination between the general practitioner and the local authority and hospital services, especially in cases which developed mental illness as a sequel to physical illness. Councillor T. M. Larrad (chairman of Manchester Health Committee) mentioned the difficulty of persuading councils, with the hospitals taken from their control, that the functions of their health committees would be more important than ever. Mrs. M. Ormerod (chairman of the Mental Health Committee of the L.C.C.) suggested the setting up in every district of a citizens' health bureau, where advice could be given by sympathetic and trained persons. She also thought that there was a reservoir of social workers among women who had had previous experience in that field and had married, but would now be prepared to return in a part-time capacity.

Dr. Kenneth Cowan (M.O.H., Gloucestershire) said that if mental health was to have the attention it deserved there must be a working partnership between the Regional Hospital Board and the local authority. Regional Hospital Boards should extend their plans beyond the curtilage of their hospitals, and local authorities should place their resources at the disposal of the Boards. Adequate access to consulting psychiatrists should be accorded to general practitioners.

Dr. R. F. Barbour (Medical Director, Bristol Child Guidance Clinic) spoke of the advantage of dissociating the psychiatric service so far as possible from the mental hospital. Interviews should take place on neutral ground, not on hospital premises. As for the cost of additional psychiatric services—a Bradford representative had expressed some fear that there might be an outcry against increased rates—he was surprised at the number of authorities who wasted the time of their trained workers by not affording them proper means of transport or adequate secretarial help. He urged the importance of preventive work in child guidance, especially in the earlier years—pre-school years—during which often the main deterioration of personality started. Dr. Mary Burbury (Manchester Child Guidance Clinic) spoke of the value of the indirect approach to parents by means of social meetings; they were not responsive to lectures.

Dr. Greenwood Wilson (M.O.H., Cardiff) urged that more use be made of the health visitor. In Cardiff they were increasing the number of health visitors from 27 to 44, and arranging that they should receive training from the social psychiatric worker, so that they would be able to advise parents on cases of mental deficiency or instability in children, and there would be no necessity to import some fresh person into the home.

A Sheffield delegate said that the Mental Health Service in his city examined all cases of attempted suicide. Such cases (which were often automatically sent to mental hospitals) well repaid careful psychiatric examination, and the examination might be extended to relatives who perhaps had contributed to the difficulty.

Dr. Rees Thomas, who had presided at this session, said that the services of local authorities in the mental health field, notwithstanding the transfer of hospitals to the Regional Boards, might well be the most important side of the health services of the country.

Education for Mental Health

The final session, over which the Earl of Faversham presided, was devoted to education for mental health as a national and international responsibility. Brigadier A. Torrie (Director of Army Psychiatry) declared that the need for information concerning the prevention and early treatment of mental ill-health was as great as the need for information concerning tuberculosis and cancer. Mental ill-health was primarily a social disease, and accordingly it was the responsibility of society to concern itself with prevention and cure. Physical hygiene was accepted

by parents, who cared for their children's nutrition and physical condition, but the need for mental care was equally great. Classes for parents could easily be arranged, but it was important also to have regard to emotional difficulties during pregnancy, and here the antenatal clinic came into the picture.

In the absence of Dr. J. R. Rees, who, it was announced, was in Denmark in connexion with the forthcoming International Congress on Mental Health, to be held in London in August, the closing address was given by Miss Sybil Clement Brown, the programme secretary of the Congress, who said that the theme would be "Mental Health and World Citizenship." Discussion groups had been at work in many countries for some months, and the results would be brought together for international exchange.

THE PROGRESS OF THE MUNICIPAL HOSPITAL

The annual meeting of the Medical Society of the L.C.C. was held at County Hall on Jan. 7, when Dr. R. C. Harkness, the retiring president, delivered his address. It was reported that the Society now numbered 349 members. Sir Allen Daley paid a tribute to the late Dr. G. F. Stebbing, one of the founders of the Society.

Dr. Harkness said that his own first experience of a municipal hospital was in the North of England many years ago, when he was appointed medical superintendent (though technically only a medical officer) of a combined institution in which hospital and workhouse were in the same curtilage, and there were two blocks for mental cases. For a hospital of 350 beds the medical staff consisted of only himself and one junior assistant medical officer. There was no consultant staff, no pathological laboratory, and such x-ray equipment as was available was in charge of a ward sister. The nursing staff numbered 70. From there he went in 1919 to the charge of a metropolitan general hospital, where he had a staff of five assistant medical officers, but three of them were allocated to district medical work and to two old workhouses, so that for 670 beds the medical staff in effect consisted of the medical superintendent and two medical officers. Again, there was no pathological laboratory, and the x-ray department was run by the theatre sister. At the same time he acknowledged that before the Act of 1929 some of the boards of guardians which were progressive in spirit made noteworthy improvements in their hospitals.

The London County Council took over the hospitals in 1930 and the first important step after that was the approval given by the Council in 1931 to a report on medical staffing. This established the basic structure of L.C.C. hospital staff which had continued ever since, though there had been many changes in detail. There were medical superintendents, deputy medical superintendents, and senior assistant and assistant medical officers. The assistant medical officers roughly corresponded to registrars in voluntary hospitals and had a limited tenure of four years. Promotion was so far as possible within the service. There was a steadily rising standard in the work done, and, of course, the better the quality of the work done by the medical staff the larger the medical staff required, because much more was done for the individual patient. The consultant position was regularized in 1933, when the so-called group system was instituted. The consultants were not given charge of beds: they were consultants in the strict sense of the word, visiting the hospital for a certain number of sessions. Nevertheless, in such specialties as ophthalmology and otolaryngology by the circumstances of the case, consultants had taken charge of beds to a large extent. In 1937 the so-called half-time obstetricians and gynaecologists were appointed.

Before the war a scheme of reorganization was worked out involving a large increase in the number of specialists and a modification of staff structure, with the setting up of clinical units of various kinds, but the recommendations were not formally presented to the Council. The position of the medical superintendent had received a good deal of consideration. In a general hospital no one man could now be held responsible for any degree of clinical supervision of all the branches of the work. What the final position with regard to the medical superintendent would be he did not know. The number of full-time specialists had been increased, and the conditions of

remuneration of many existing officers had been improved, but the basic structure had not been altered, and with the hospitals about to pass under regional authority it did not seem desirable that any large reorganization should be entered upon: it should wait the new conditions.

One possibility was that the fever hospital would disappear, fever cases being dealt with in a branch of the general hospital. Yet just as in ophthalmology it had been found advisable that all ophthalmic cases should be treated at the general hospital there should be one highly specialized ophthalmic hospital, such as Moorfields, so it might be found justifiable to run one highly specialized fever hospital.

THE DOCTOR'S PART IN CRIMINAL INVESTIGATION

Another lecture for final-year students and newly qualified practitioners, arranged by the Metropolitan Counties Branch, was given at B.M.A. House on Jan. 6 by Dr. C. Keith Simpson.

Dr. Keith Simpson reminded his audience that the reason why the doctor's assistance was so often invited in criminal investigation was because of his professional equipment and knowledge and also because he was a man trained in sound observation and in making proper deductions from what he observed. What was it that the law required of a doctor? The law did not require him to be a sleuth; he was not asked to interest himself in criminal investigation as such: he was there to make his accurate and leisurely professional observations, and to draw from them any reasonable inferences. If he had had a good training and had retained, say, not less than 90% of what he had been taught, he would as a rule afford the police good service. His duty was to make entirely impartial observation, and he should remember when he was asked to assist the police that the Crown was not out to prosecute the individual but to prosecute the truth.

The lecturer went on to describe what should be the procedure of the doctor—meaning the ordinary doctor, not one claiming special knowledge of criminal investigation—when called to examine the victim of a fatal accident or of presumed murder. His first duty was to make sure that the victim was dead. Suspended animation, especially in electrical accidents, was not uncommon, and in cases where there was a doubt means of resuscitation should be sought. If the victim was dead a point of importance was to determine how long it was since death had taken place. The temperature should be taken by the ordinary thermometer, preferably in the rectum or armpit. By the time an expert had been called in the body might be completely cold and evidence on this point be lost. His next duty was to recognize any signs of foul play. The position of the body might give rise to suspicion. The scene of the crime, if such it was, should be disturbed to the smallest extent possible. Nothing should be handled which would take a finger-print. But the doctor should not be so cautious in his approach as, for example, to fail to look for evidence of asphyxiation, which was the form of death most common in the victim of sexual assault. Manual asphyxiation was something which could only spell crime, for it was impossible for a person manually to strangle himself. Injuries which might or might not be suspicious were those caused to the side of the face by contact with a hard surface. Some injuries plainly suggested a street accident; others could have resulted only from very deliberate blows. In stab injuries those which were self-inflicted were often characterized by feeble scratches by the suicide who timidly stroked his throat or wrist with the weapon before making the fatal wound. Most suicides shot themselves through the temple, the mouth, or the middle of the forehead, and if the wound was not in the usual situation it was always a matter for suspicion. One should also look for any signs of resistance on the part of the victim.

Dr. Keith Simpson, whose lecture was illustrated by lantern-slides and was greatly appreciated by the large audience, concluded by saying that if the doctor had made sound and reasonable observations he need fear nothing in the witness-box, and he must not imagine that he was being urged by the authorities to go any further than his scientific investigation warranted.

THE ROYAL SURGICAL AID SOCIETY

The Lord Mayor of London presided over the 85th annual meeting, at the Mansion House, of the Royal Surgical Aid Society. It was reported that over 19,000 appliances had been supplied during the past year, an increase of more than 1,000. Nearly 7,000 of the appliances were trusses, and nearly 4,000 were stockings and knee-caps. The list included 293 artificial legs and 1,639 high cork and special boots. Appliances are supplied only in accordance with surgeons' prescriptions. It was mentioned by one of the speakers that the high and still rising price of all appliances is a matter of concern. It may not be generally known that many surgical appliances require the surrender of coupons, also that further coupons are necessitated by reason of the wear on the clothing which the appliances often cause.

In responding to a vote of thanks to the surgeons of the Society, which was proposed by Mr. R. E. Goodfellow and seconded by Major-General E. H. Fitzherbert, Mr. Cecil Flemming said that it was embarrassing to be thanked for something one naturally liked doing, and to be a surgeon for such a Society was an enjoyable occupation. The surgeons were the people who came into contact with the patients and were best able to judge what the help given meant to them. With regard to the durability of the appliances furnished by the Society, he mentioned that recently a man came to the Society's offices complaining that his belt was wearing out. On being asked when it was supplied, he said that it was in 1904.

Financially it was reported that the subscriptions and donations had been well maintained and had increased slightly. There was nothing in the National Health Service Act to indicate any intention on the part of the Government to take over the Society or its work. Despite the far-reaching effect of the Act, the annual report stated that it was "apparent that the work of the Royal Surgical Aid Society will be required for many years to come, and it would be tragic if its income should fail because subscribers feel that its work may become a Government responsibility." Other speakers at the meeting included Alderman and Sheriff Sir Leslie Boyce, Admiral Sir Martin Dunbar-Nasmith, and the Rt. Hon. Thomas Wiles.

MEDICAL FOUNDATION OF EPSOM COLLEGE

The Royal Medical Foundation of Epsom College appeals to all members of the medical profession who do not already do so to subscribe to the Foundation. "In every profession some must fall by the wayside; others must inevitably fall upon evil days. Our object is to help the families of these less fortunate brethren. To that end the Foundation in 1947 has provided:

50 ordinary pensions	£ 1,500
43 Foundation scholarships for boys (educated, clothed, and maintained entirely free of cost)	8,010
13 scholarships for girls	570
24 Council exhibitions for boys	1,500
140 pensions and annuities of varying amounts	3,023
Grants towards education of 51 boys and girls	1,443
Grants to widows and spinsters	339

"This is an expenditure of £16,385 in the year. In order to maintain this assistance we have to rely upon the generosity of our subscribers and donors for over £10,000 per annum. Without sufficient help from them even our existing benefactions would have to be curtailed. Owing to lack of funds many deserving applicants—medical men and widows, and children of school age—remain unassisted. The Sherman Bigg Fund enables the Foundation to make educational grants for those who cannot obtain scholarships. Donations to augment the income of this Fund will be most welcome. We have many applicants on the list for pensions—both widows and spinsters, all hoping for help some day, some of whom have been waiting for years.

"We therefore beg you earnestly to send either a subscription or a donation to this Foundation during 1948. When doing so you may, if you wish, stipulate the particular form of benefaction on which it is to be expended. Subscriptions and donations may be sent to the Secretary, the Secretary's Office, Epsom College, Surrey, by whom information will be sent on request."

ORDER OF ST. JOHN OF JERUSALEM

The *London Gazette* has announced the following promotions in, and appointments to, the Venerable Order of the Hospital of St. John of Jerusalem:

As Knights: Major-General Sir Robert Hay, K.C.I.E., K.H.P., I.M.S., Brigadier W. W. S. Johnston, C.B.E., D.S.O., M.C., Colonel H. H. E. Russell, O.B.E., V.D., Colonel E. Cotter, C.I.E., V.H.S., I.M.S., and Dr. H. F. J. Norrie. *As a Dame*: Dr. Frances C. B. McKay. *As Commanders (Brothers)*: Major-General F. A. Maguire, C.M.G., D.S.O., V.D., Colonels N. Briggs, C.I.E., V.H.S., I.M.S., and L. H. A. R. Huggard, Lieutenant-Colonel E. A. H. Russell, V.D., Messrs. R. D. A. Douglas, M.B.E., H. R. Rishworth, C.B.E., J. J. Abraham, C.B.E., D.S.O., and Drs. W. Benton, C. D. Newman, S. F. Chellappah, O.B.E., and E. S. Bowes. *As Officers (Brothers)*: Air Marshal T. E. V. Hurley, C.M.G., C.B.E., Colonels T. E. Holland and A. M. McIntosh, Major A. Ehrmann, O.B.E., T.D., Captain C. J. Evers, Mr. F. H. Edwards, Drs. T. P. Lalonde, F. W. Hobbethwaite, E. P. Scott, D. M. MacManus, W. Megaw, J. C. D. Carothers, R. V. S. Cooper, C. R. de C. Sadler, E. H. Lodge, F. C. Middleton, M.B.E., J. Mackenzie, and R. C. Inglott, M.B.E. *As Associate Officers (Brothers)*: Major D. P. Mitra and Dr. R. S. B. Gopal. *As Officer (Sister)*: Lady Margaret Ramsden, M.D. *As Serving Brothers*: Surgeon Captain C. T. Baxter, R.N.(ret.), Brigadier W. Leslie, M.C., T.D., Major G. K. Wood, R.A.M.C., Drs. E. J. A. Dougan, T. H. McOwat, M. A. Oulton, L. D. Densmore, J. F. Eustace, W. D. Dyson, E. W. C. Thomas, F. W. Moffitt, W. L. Jack, R. N. Gibson, H. D. Wallace, E. J. G. Wallace, W. G. Denholm, L. C. J. Edwards, J. G. Bremner, H. C. Geldard, J. W. Flynn, W. E. George, H. H. Hurst, and D. J. Taitt. *As Associate Serving Brothers*: Captain M. Solomon, R.A.M.C., and K. B. M. S. Mahmood. *As Serving Sisters*: Drs. Eda S. Curtis, Helen M. McNeill, Olive S. May, Marguerite A. C. Douglas-Drummond, and Laura K. M. Horne.

Reports of Societies

ORTHOPAEDIC SURGERY IN RHEUMATOID ARTHRITIS

At a meeting of the Section of Physical Medicine of the Royal Society of Medicine on Jan. 14, Mr. W. A. LAW, who has recently spent some months at the Massachusetts General Hospital studying the orthopaedic services of Bauer and Smith Petersen, discussed the part played by orthopaedic surgery in rheumatoid arthritis and ankylosing spondylitis.

Mr. Law said that the orthopaedic surgeon had lately been taking a greater share in overcoming the deformities of these common diseases. For this purpose a high standard of team work was essential, the team including a physician, an expert on physical medicine, an orthopaedic surgeon, and in certain cases deep x-ray therapy might also be needed. The principle of rest was still the basis of the so-called conservative treatment of rheumatoid arthritis. The aim of all treatment must be to relieve pain, arrest the disease process, and restore function; but rest might be harmful from the point of view of restoration of function, particularly if by putting one joint at rest there was interference with the function of other joints of that limb. While a case was undergoing surgical treatment a careful balance must be preserved between rest and active exercise, pain being controlled if necessary by drugs. In many rheumatoid cases there were multiple deformities necessitating a long programme of reconstructive or functional treatment. The patient might also have to undergo one or more revision operations to secure a satisfactory end-result.

Upper Limb

He proceeded to discuss, with illustrative cases, the orthopaedic procedure for various joints affected by rheumatoid arthritis. A painful shoulder joint with adduction and internal rotation deformity was frequent; excision of the acromion process, together with removal of sub-acromial bursae, eliminated the source of pain and allowed free movement. Relief of pain also helped to remove muscle spasm. In rheumatoid arthritis of the elbow joint, spasm of the biceps muscle was a pronounced feature. Smith Petersen had drawn attention to the fact that the radial head might be drawn upwards so as to impinge upon the capitellum. Excision of the head of the

radius overcame such faulty joint mechanics, pain was relieved, and a considerable improvement in range obtained. Arthroplasty of the elbow joint with excision of the lower end of the humerus and upper ends of the radius and ulna was indicated where there was gross joint destruction or complete ankylosis.

Lower Limb

The hip joint and the knee joint frequently demanded surgical treatment on account of pain and deformity associated with a variable degree of ankylosis. Where the patient's morale was low and the muscles wasted and fibrotic a stabilizing procedure such as arthrodesis might be useful. In too many cases the problem of bilateral painful stiff hips and/or knees had to be faced. A strong plea was made for a reconstructive operation before fibrosis of muscles and ligaments and atrophy of the bones and joints had progressed too far. More than one operation might be necessary.

In 1939 Smith Petersen announced his technique for the performance of arthroplasty of the hip, his aim being to create all the elements which made up the joint. This technique had been greatly improved by the introduction of the vitallium mould. Originally a two-stage procedure was intended, but the inertness of vitallium had now made the second stage (for mould removal) unnecessary. The mould became a permanent insurmountable barrier to recurring ankylosis. Any reconstruction of the hip joint must aim at producing a joint which was painless, stable, and capable of bearing weight. The response to the procedure was conditioned by the degree of muscle wasting and involvement of other joints, but even in bed-ridden cases there was marked improvement. In a few patients increased use of the hip joint resulted in pain and effusion in the knee joint, but this was temporary.

Mr. Law reviewed four types of reconstruction: (1) routine arthroplasty in which the femoral head and enlarged and deepened acetabulum were reshaped and made smooth and congruous; (2) the modified Whitman procedure, which was indicated if the femoral head had undergone atrophy or the bone was so soft that after reshaping by gouging the femoral neck became too short; (3) the modified Colonna operation, which was carried out if there had been a more severe degree of absorption or loss of the femoral head and neck; (4) arthroplasty at the level of the lesser trochanter, should the greater trochanter be unsuitable for reshaping. This last operation resulted in loss of leg length, but this was of little significance in bilateral cases.

Painful and swollen knee joints could always be rendered painless and stable by arthrodesis. In cases where the joint was grossly distended by synovial effusion or the synovial membrane was thickened, much might be achieved by excising the synovial membrane so far as possible, together with the semilunar cartilages. Internal derangement of the knee joint owing to a meniscus lesion in a joint with rheumatoid arthritis should be treated by excision of the meniscus. In performing posterior capsulotomy difficulty might be found owing to dense adhesions. Subperiosteal stripping of the capsule might prove a safer method. As a less radical alternative to the complete excision of the patella, plastic operations on the bone were of value, and it was possible that the retention of a portion of the patella aided in repair and improved the quadriceps mechanism.

After touching on the spinal osteotomy operation devised by Smith Petersen, Mr. Law concluded by saying that these joint reconstructions were formidable operations, requiring patience and vision on the part both of surgeon and patient but the benefit was seen not only in the restoration of function but in the marked improvement in the patient's outlook always an important factor in the treatment of rheumatoid diseases.

Discussion

Dr. W. S. TEGNER, President of the Section, referred to a case which Mr. Law had mentioned of a man who after arthroplasty of the elbow sustained an elbow injury on being lifted from the ambulance, whereupon the rheumatoid condition flared up again. It was interesting to learn that joint which had been treated surgically were still subject to the possibility. At what stage should operation be attempted? Those who saw a good deal of rheumatoid arthritis most

believed that movement should be undertaken early. Was it possible that in a joint which had been treated by arthroplasty a recurrence of rheumatoid arthritis might occur as bad as, or even worse than, that in a joint on which no operation had been done? Mr. Law appeared to think that rheumatoid arthritis and ankylosing spondylitis were very much the same condition. On this side of the Atlantic most people thought they were not the same.

Mr. LAW said that there was no doubt that a joint which had undergone arthroplasty was still subject to any disease process to which the unoperated joint was subject. Rheumatoid arthritis might recur in a joint on which an arthroplasty had been done. The main value of arthroplasty at such a stage in the disease was in the maintenance of muscle power. If the old idea of waiting until the disease had "burnt itself out" still obtained, the muscles and fascia by that time would be just ribbons of fibrous tissue. There were no soft structures with which to work. Hence the value of the teaching of Smith Petersen on the necessity of considering revisions of these operations. An arthroplasty on the hip joint, done to-day, might result in six months' time in a flexion range of 60 to 30 degrees, but in eighteen months' time the range might have come down to 30 to 40 degrees, and if there had been further flare-ups there would be more pain and more joint swelling, and it would be worth while revising that arthroplasty. In the hands of Smith Petersen that procedure worked extremely well. But it was a colossal programme to put to the patient. With regard to ankylosing spondylitis and rheumatoid arthritis, he felt that there was a difference in the state of the bone as between the two conditions, but it was not a gross difference. In the former condition the bone was much harder, so that one had to use hammer and osteotome to get through the bone, whereas in the ordinary rheumatoid case one could often do the gouging by hand. Rheumatoid bone was more vascular and was associated with the thick overgrown villi, so that there was more bleeding in the operation.

Dr. FRANK COCKSEY said that the practice in this country in the active stage of the disease was to rest the joint as much as possible and maintain prophylactic movement rather than institute active exercises. He found it difficult to believe that the same flare-up after operation might not occur as was sometimes seen in their own unoperated cases which, after conservative treatment, were allowed to get about too soon. Was there any evidence that by operating early the period of activity of the disease was shortened?

Mr. LAW replied that there was no evidence on that last point. The benefit of early operation was the maintenance of muscle power and tone. Joint movements were dependent on these muscles. If they had been reduced to mere ribbons of fibrous tissue no chance was given for joint reconstruction. He would not say that early surgery should replace conservative treatment. He thought that the patients must have their proper medical treatment before any surgery was considered. But he felt that there was a place for surgery before the disease was "burnt out." There was a point where conservative treatment (splintage, traction, and various therapeutic measures) ceased to make for real advance, and this was before the muscles became completely atrophied. That was the ideal time to begin to think of surgery.

Maxwell apparatus), this being a convenient figure, and, as the pressure change produced by each discharge of the cylinder can be read on the manometer while the cylinder is being recharged, the operator can carry out a large refill clinic using the plunger only. The aspiration of air from the chest calls for exactly the same procedure—the connexion having first been transferred from the outlet to the inlet after removal of the filter.

By using this cylinder connected to a manometer we have been able to reduce our refill clinic time by one-quarter. This

Diagram of cylinder.

Photograph of cylinder. The filter has been removed from the inlet tube and laid beside the cylinder.

Preparations and Appliances

SIMPLIFIED APPARATUS FOR COLLAPSE THERAPY

Dr. FINTAN L. CORRIGAN, Military Unit, Harefield County Hospital, Middlesex, writes: The cylinder shown below was designed to simplify the apparatus at present in use for collapse therapy and to produce, if possible, a fool-proof machine. By the use of automatic valves at the inlet and outlet allowing air in one direction only, the machine is at once independent of taps, and refills can be given by use of the plunger only. However, a tap is desirable between the cylinder and the manometer for the following reasons: (1) To control the rate of flow of air (the tap being set to the desired speed beforehand); (2) to take pressures at more frequent intervals than 200 ml. if required. The capacity of the cylinder shown is 200 ml. (as in the

speed can be maintained when the operator has to manipulate the apparatus for himself, in contradistinction to the use of an apparatus with taps. The cylinder shown was made to my design at the hospital by a member of the engineering department (Mr. A. Barons) and is at present being used with an aneroid manometer as fitted in the Maxwell box, a tap being incorporated between the cylinder and the manometer. It is, of course, essential that the valves should be accurately machined.

I am indebted to Dr. K. R. Stokes, the Medical Director of Harefield County Hospital, for his help and encouragement in producing this modified apparatus.

Correspondence

The Issue is Freedom

SIR,—The Minister of Health has refused to consider making any amendment to the National Health Service Act, 1946.

If we take service under this Act, we shall be subjected to serious encroachment on our liberty, both professional and personal. This applies to consultant and specialists as well as to general practitioners, but it is the general practitioners who will be most obviously affected.

This is how the Act will curtail the freedom of the general practitioner :

1. His practice will no longer belong to him but will become the property of the Minister of Health of the day. The doctor instead of being the owner will be reduced to the status of tenant.

This clearly involves a loss of freedom.

2. He will no longer be able to make his own arrangements to move from one area to another. If he wishes to move he will have to get the consent of (a) the Local Executive Council of the place he wishes to go to; (b) the Central Medical Practices Committee in Whitehall; (c) the Minister of Health of the day.

This is another loss of freedom.

3. He can be dismissed from the Service on the personal decision of the Minister of Health of the day without right of appeal to the courts.

This is a grave loss of freedom. He is deprived of the rights which are enjoyed by every other citizen.

4. The Minister has unparalleled powers under this Act. One of them is the right to appoint a large proportion of the members of all the important committees concerned with the administration of the Act, and above all the right to appoint the chairman. This includes the Local Executive Councils, to whom the general practitioner will be directly responsible. A bad or biased chairman can wreck any committee and completely obstruct its activities. The chairman appointed by the Minister can be removed only at the Minister's pleasure. Thus the members of the committees are helpless and have no control over their chairmen.

This is a grave loss of freedom. It resembles the set-up of the Fascist corporations by Mussolini in Italy.

5. The Minister of the day has the power to alter the terms of remuneration and the conditions of service by Regulation. This means that without having to obtain the consent of Parliament he can arbitrarily fix or vary the amount of income that a doctor can receive whether by way of salary or capitation fee. Regulations have to be laid on the table of the House for a relatively short period, and unless someone makes a prayer for their annulment within this time (a prayer which in practice hardly ever succeeds) they automatically have the force of law. This means that the doctor has no security, since every new Minister of Health can vary the remuneration and conditions of service at his pleasure.

This is a dangerous loss of freedom.

6. The present Minister proposes to pay a basic salary. Thus the general practitioner will become a salaried servant of the State. This inevitably involves Civil Servant status and is the thin end of the wedge to whole-time salaried service. The present Minister said in Parliament in 1946 words to the effect that the time was not yet ripe to make the general practitioner a whole-time salaried servant. This shows that it is his ultimate objective. In any case the next Minister or any subsequent Minister can do this by simple Regulation.

This is one of the gravest losses of freedom.

Taken together all these encroachments on freedom will leave the general practitioner and, in the long run, the consultant and specialist also at the mercy of the Minister of Health and of the Government which he represents.

Governments and Ministers come and go and their political outlook varies. The doctor will be subject to political pressure and a loss of freedom.

His patients must suffer because they are no longer his employers; his loyalty is not to them but to his master the Minister and to the Treasury on whom his livelihood depends.

Once in the Service there can be no going back. Private practice will be crushed out or will be so precarious that very few doctors will be able to risk it.

Thus there is no alternative, and that in itself constitutes a grave threat to freedom.

At the first meeting of the World Medical Association held in Paris in September, 1947, the future relations of the doctor to the State were discussed. Delegates from many countries said that the freedom of the medical profession in their own countries was in serious jeopardy. They stated that the eyes of the world were on the British doctors, and they prayed that we should have the wisdom and the strength to stand out for the preservation of our freedom, for if we permitted it to be taken from us this would lead to the enslavement of Medicine to the State all over the world.

To accept service under this Act is to accept servitude.—I am, etc.,

Bournemouth.

DORIS ODUM.

Working Hours in N.H.S.

SIR,—The thing most noteworthy is that no Labour spokesman, big, medium, or little, nor any Labour newspaper, dared to discuss doctors' working hours in the N.H.S. They know too well how impracticable the scheme is under their trade union hours but have not the courage to say a twelve-hour day with the other twelve on call will be required.

The value of the salaries offered cannot be assessed apart from the hours of work required, but the Minister does not dare to state them. His own party and the rest of the public would be too shocked if he did.—I am, etc.,

Birmingham.

W. J. BURNS SELKIRK

Remember Willesden

SIR,—We are being alternately coerced and invited by Bevan to sit under a "sword of Damocles." This is our last chance to answer "No" in a voice of thunder that shall penetrate the obsessed brain of the Minister, but some apparently would feel quite safe if they were allowed to own the chair they are to sit on, oblivious of the real danger above.

Let us consider the position when the entire nation becomes compulsorily insured by the State. A middle-class or professional man with a wife, three older children at school, and a daily maid will find his multiple "five and tuppences" amounting to a tidy yearly sum and will not for long afford the luxury of a private G.P. or consultant. The estimate is 95% State patients, leaving 5% for private practice. What are the implications? Many now realize that a basic salary, so helpful for beginners, may mean the thin end of the State wedge when it is capable of being increased to 99% by Regulation. But a capitation fee can lead the same way when there is no private practice to fall back on as at present. Should we offend the Minister, our quarterly cheque would cease to arrive. We should face starvation not for a medical but for a political offence. The Willesden incident showed up the Minister's hand quite clearly, though prematurely, for the profession is not yet in the bag.

Again, what in the name of logic is the use of owning the goodwill of a practice from which one can be "fired" without redress by a tribunal of three, of which only one is a medical man, with no right of appeal whatsoever? Are we to be the first section of the nation to be deprived of what has been the right of every Englishman since the time of King John—the right to be tried by his peers: "for to none will we deny, sell, or delay right or justice"? Are we to allow the clock to be put back to the evil days of tyrannical injustice normal here before Magna Carta? To divide the profession by setting the divergent interests of G.P.s, consultants, salaried M.O.s, and young ex-Service doctors against each other is a skillful technique too familiar to be pleasant. If we are duped we shall be the first sad link in the chain of fettered trades and professions which would follow. The three wise Presidents of Gotham, versed in courtcraft, urged us to negotiate, foreseeing that otherwise we should lose the sympathy of a bewildered

from having banged them for a wasted year against a brick wall.

Is there no escape for patient or doctor? If all are State-insured and the doctor is paid by the State, then neither a patient fee nor ownership of one's practice can be a safeguard without justice, and, as Clause 42 now stands, since the Government defeat in committee there is no appeal whatever from the decision of the tribunal open to a disqualified practitioner. "Power corrupts, but absolute power corrupts absolutely." A man must live, but I am prepared to starve for this one fundamental principle of justice (and my wife agrees with me); without it the rest are shadows. We shall come to the Minister's menials unless we vote "No" to his biological fantasy.

If all must be State-insured an alternative is for the patient to choose his doctor, pay his G.P. or specialist a prescribed fee for services rendered, and for the State to repay the patient. This would avoid political tyranny.—I am, etc.,

E. Dereham, Norfolk.

E. PUDDY.

Helmley, Yorkshire.

ALEXANDER C. BLAIR.

The Younger Generation

SIR,—I am in whole-hearted agreement with the views expressed in Dr. Sybil Tremellen's letter (Jan. 10, p. 69). If, however, there is truth in the statement that "too many younger members of our profession are terribly afraid of insecurity and seem to prefer safety to freedom," I would like to encourage her, and the medical profession in general, by stating emphatically that this is certainly not true of those of us who have yet to qualify. Let it be remembered that the majority of present-day preclinical medical students have served in the Forces, and that most of us will be 30 or thereabouts by the time we have finished our course, and, although not afraid of insecurity, are consequently extremely cognizant of the dangers of State control.

As at present our opinion is ineffectual it is the responsibility of the medical profession to stand fast and ensure that the addition of which the profession is so justly proud is handed on to those of us who have yet to uphold it.

Although unable actively to involve ourselves in your struggle against Mr. Bevan, I feel duty bound on behalf of the thousands of similar thinking medical students to express our confidence in the profession's ability to maintain that freedom which will enable us to qualify as doctors and not become State servants once more.—I am, etc.,

St. Bartholomew's Hospital Medical College. GERALD C. WATMOUGH.

SIR,—May I as a young doctor whose philosophy is not of the sterile safety-first variety reassure Dr. Sybil Tremellen, who appears disturbed according to para. 2 of her letter (Jan. 10, p. 69)? Most of my contemporaries are against a whole-time State Medical Service, of which the present scheme is clearly the thin end of the wedge.

The good will between and the combined efforts of the doctors themselves comprise the effective force in any health organization. This can be maintained only by preservation of the profession's high principles in their entirety. The Act in its present form sabotages these principles.

Close study of the Act and of the Minister's statements reveals his stratagems as *réchauffé* and unconvincing. The attitude of the intransigent Mr. Bevan to our spokesmen suggests that he regards the intended National Health Service as a *fait accompli*. Let us disillusion him. By dint of trade unionism the *coup de grâce* may be implemented by the forthcoming plebiscite.

If this linchpin of the Socialist programme is not established in "annus mirabilis the third" of the present regime, then Mr. Bevan will surely forfeit his mandate. His successor may be less biased and more reasonable. Politicians are ephemeral, the Health Service is lasting and must therefore be as perfect as possible at its inception.

Let the profession exemplify by a united stand that it can halt the tidal wave of Socialist compulsion.—I am, etc.,

"SERVING OFFICER."

Action and Reaction

SIR,—The letter by Dr. Dan E. Davies (Jan. 10, p. 70) is perhaps not without significance, both on account of its direction and its ethical content. It is refreshing to have such a

decided opposition to the general run of the correspondence appearing in your columns weekly. I suppose there are others who hold similar views. The danger is that their misinterpretation of obvious facts may mislead others at this time. The figures so confidently quoted may have some relevance. But it is not figures we are chiefly concerned about so much as the general bias of the Minister's whole attitude, and his unflinching refusal to budge an inch. Like many of my fellow practitioners I am of opinion that it is quite hopeless to expect consideration or fair play from him.

With some young doctors at the outset of their medical career there may be some excuse for a period of vacillation during the present crisis: with the majority of practitioners of standing I can see none. And I do not believe there is really any occasion for a plebiscite. But if it can clear up our position let us have it by all means. Will I enter the new Health Service in July, 1948? Not if I can possibly help it.—I am, etc.,

SIR,—Mr. Bevan appears to be determined not to amend his Health Service Act. Possibly he believes that all its provisions command the support of a majority of the electorate. But it is more probable that his stubbornness is supported by a conviction that this Act, as far as possible, embodies those general principles for which he and his party stood at the last General Election. Indeed it is not at all easy to deny the Government's mandate for this Act, especially as in so many respects it falls short of the full-blooded Socialist principles held by a large section of the House of Commons. Furthermore, there would appear to be little general justification for the plea that the Government in framing legislation should cater primarily for the principles of that section of the public which has the greatest personal interest in it. On the contrary, many would feel on sounder ground pointing out that this Government's legislation already shows far too much sectional influence of that sort.

On what basis, then, can we justifiably claim a right to demand amendment of this Act? Surely if we can do this at all it cannot be by insisting that Mr. Bevan should adopt the general principles of an interested minority rather than of those he is supposed to represent. We must demonstrate to everyone that a large majority of the profession by reason of its expert status is honestly convinced of certain definite errors in the Act. But in fact what steps are we taking in the matter? There is to be no attempt to ascertain what majority of the profession is opposed to any particular provision of the Act; the sole source of any specific guidance upon that must still be sought in the original questionnaire. After Dr. Hill had addressed a recent meeting of the local profession more than one questioner raised this point. But Dr. Hill in his replies would not allow that individual members should be asked for anything more or less than wholesale support (or opposition) of the entire list of points upon which the B.M.A. opposes the Act—these points being derived from principles which are by no means the product of machinery democratically comparable to that of a plebiscite.

Doubtless some doctors support the entire Act, while others subscribe to the whole range of B.M.A. opposition to it. However, the probability is that the majority of the profession is to be found dispersed between these extremes. It would therefore appear that the B.M.A. intends to combat Mr. Bevan's indiscriminating thrusting of the Health Bill with an equally comprehensive and uncompromisingly exerted force in the opposite direction. A doctor wishing to express his opposition to some clause in the Act, which the vast majority believe to be vital, is obliged to wager his livelihood in support of other issues which he does not believe the majority of the profession would consider worth while.

This blunderbuss plebiscite is going to rob the B.M.A. of many votes that would have strengthened more specific opposition to the Act. And if the B.M.A. and the Negotiating Committee should nevertheless receive a mandate to oppose Mr. Bevan on broad principles, they will still be in a very unsound position to claim that they have anything like wholehearted support when it comes to pressing a reasoned case against each controversial clause of the Act. Indeed, at best, the position will only be changed in so far as the doctors

can point their blunderbuss at the heads of Mr. Bevan and everyone else who sponsors his legislation. At worst, those comparatively few vital issues for which long before now we should have united will finally go under—once more swamped in a sea of relatively unessential or controversial matter.—I am, etc.,

Eye, Suffolk.

J. SHACKLETON BAILEY.

Young Practitioners

SIR,—As an elderly G.P. of more than a quarter of a century's standing may I be allowed to voice the very genuine fear of many young practitioners? Of recent years they have come out of the Forces; have bought a practice or share of one; have settled down with their young wives and families, perhaps two or three children from a few months to six or seven years of age; and are enjoying for the first time the bliss of a happy married life. Their practice is their daily bread-and-butter, and, while wholeheartedly agreeing with what the B.M.A. has done and is doing, they are most apprehensive about the future. The loss of capital which they will incur by staying out is bad enough, but to look at their homes and families, and then to go out and cut the very ground of livelihood from under their feet, is asking a very great deal from them, and many will not be able to do so.

To such men the B.M.A. must give some assurance. For many years we have been building up funds for such an emergency. I know not to what these funds amount, but I believe it is over a quarter of a million, and, if so, the B.M.A. might consider helping some of these men over the interim period. I am a "die-hard," and, though I should like to have been allowed to carry on my practice for a few more years, nothing will induce me to join the Service as it now stands.—I am, etc.,

Chipping Norton.

J. C. RUSSELL.

Ownership of Goodwill

SIR,—At a recent meeting of the Labour Party in Marylebone Major Duncan Bruce, Principal Private Secretary to Mr. Aneurin Bevan, gave an able explanation of the health services under the Health Act. Among other things he said that: (1) *At first* the pay-beds in hospitals would be set aside for those who wished to buy privacy and that consultants would be able to charge fees on a sliding scale in other beds; (2) voluntary effort was ingrained in the character of the British people, and full scope would be given for that in the new Health Service; (3) the Government would no longer allow doctors to own the goodwill of their practices, because in the past the custom of buying and selling practices had been sometimes abused.

It is well that the medical profession should realize that an uncompromising spirit pervades the official utterances of those who are forming the Health Service of the future and who expect the medical profession to co-operate with them. When the speaker was asked why those doctors who wished to remain independent in the National Health Service should not be permitted to do so, owning the goodwill of their practices and introducing their successors or partners, he replied that in his opinion committees were far more likely to choose the best man for the practice than the doctor who was retiring. While it must be admitted that a State service would involve committee rule and negative direction for a large number of doctors in present-day conditions, can this be any possible justification for abolishing all independent public practice? As the Voluntary Hospitals are being mercilessly cramped into a unified system, it is difficult to regard the invitation to voluntary work as serious or honest.

It is fortunate that we have been forewarned as to what the future holds by responsible Ministry officials by using such expressions with regard to the conditions of service as "at first." Dragooming or bureaucratic direction are bound to follow with the establishment of the State Service unless safeguards are insisted upon for those in the Service. For the public who demand independent service there must be even stronger safeguards, so that independent hospital, partnership, consultant, and general-practitioner service may be perpetuated.

What is it then that the medical profession considers essential in the Act and which will satisfy them in recommending service

(1) *Administration*.—That the present Central Advisory Health Council should become an Executive Body in the sense of the Coal Board and the Central Electricity Board and other undertakings.

(2) *Independence*.—(a) That consultants and specialists should retain a service independent of the State Service by the pay-blocks of hospitals remaining outside the Service and any pay-beds within the hospitals which can be allocated from hospitals that have no pay-blocks; that existing nursing-homes and all hospitals which can remain self-supporting with upkeep contributions should remain outside the Service, and that full permission for nursing-homes and existing clinics to have full facilities be recognized. (b) General practitioners who go into the Service should be allowed to retain the goodwill of their practices if they so desire it and not be merely compensated. They should have full rights to introduce their own partners and successors.

(3) *Direction*.—That there should be no direction by negative or positive means.

(4) *Remuneration*.—That there should be no salaried element for general practitioners.

Briefly, Ministerial intention to monopolize medicine must be met by a united profession protecting the interests of those who wish to go into the Service as well as those who elect to stay out.—We are, etc.,

E. T. WRIGHT.

GEORGE ROSSDALE.

London, N.W.8.

SIR,—The Minister of Health states: "There will be amending Acts, without any doubt, and the scheme will be so bettered and remoulded as experience is gained. But first it has to be begun. . . ." An amending Act after the scheme has begun certainly cannot revise the clause dealing with ownership of goodwill. The Minister intends to spend £66,000,000 of the country's money on what a large proportion of general practitioners are unwilling to sell and on which the country can never again realize the capital so expended. Let us seriously ask ourselves the reason why.

I, together with many of my fellow practitioners, consider not only that with the loss of ownership of goodwill we should lose a large part of our personal freedom but that our future negotiating powers with the Ministry would be reduced to practically nil.

What, also, would be the position of the young man embarking on general practice? Presumably he would join a "pool" and await his turn to be sent as assistant to wherever there might be a demand (I doubt whether he could reasonably expect a "view" to partnership). Later he might hope to be sent to "put up his plate" at £300 p.a. in an "under-doctored" area, where all the patients, with the exception of a few malcontents, were perfectly satisfied with the doctors of their choice; eventually he might hope to fill a vacancy through the death or retirement of an established practitioner.

With the loss of ownership of goodwill we should not only lose the freedom we have heretofore enjoyed but we should lose that freedom to all posterity. Other matters with which we disagree may possibly be rectified later by an amending Act, but not this vital point.

The Minister also states: "A failure to co-operate can redound only to the detriment of the people. . . ." yet although by entering into negotiation we have shown our willingness to co-operate, it would appear that he himself has failed to do so. I will therefore conclude with what I hope may be a constructive suggestion. Let there be an addendum to the plebiscite questions—viz., "Are you willing to accept service under the Act if the Minister undertakes to forgo his demand to purchase the goodwill of practices and to introduce an amending Act accordingly?"—I am, etc.,

Kirkby-in-Ashfield, Notts.

J. D. DURANCE.

SIR,—In your issue of Jan. 10 (p. 72) there appeared under the heading "Remuneration in N.H.S." a letter from Dr. W. Maxwell Penny in which he cites the terms offered to a young doctor presumably for the purposes of purchasing a share in a practice. It is quite outside my province to enter into any discussion of the National Health Service terms, but as there is a major error in the illustration given I feel that this should be corrected.

Dr. Maxwell Penny states that the doctor concerned would be called on to "repay the capital at 12% per annum—£30 per quarter on £1,000—in ten years. So for £1,000 he would have

leading thoughts on CHILBLAINS

.... remembering last winter's high incidence of chilblains
not only among chronic cases but in many first-sufferers

.... considering how best to protect chronic sufferers
from the same cause and effect this winter

These thoughts lead to the effective *prophylactic* measure that Colloidal Calcium with 'Ostelin' provides. Three to five injections of this colloidal solution of calcium and vitamin D are normally sufficient to see the patient safely through the winter. If the tendency to chilblains persists, a further reinforcing course should rapidly restore the circulation in the skin capillaries to normal. Injections are painless and the course is inexpensive.

HANDS AND THE MAN . . . No. 1

Mr. . . . ,
Specialist in Abdominal Surgery

When clever hands move with calm speed to the crux of the operation—then the ligatures which complete the job must be equally perfect. The Ethicon organisation holds the enviable, but highly responsible, post of leadership in sutures. Their achievement is not so much that they make more sutures than anyone in the world—but that they make sutures which are outstanding in quality and reliability.

Various sizes of Ethicon Sutures obtainable from our usual Surgical Supply House.
 All Ethicon Sutures sold in Great Britain are entirely British made.

Queues . . . Shortages . . . Harassed nerves

Because of present-day conditions—so many worries, so many minor irritations, so many hours spent in queues—more and more people are feeling the need for a general tonic. Livogen, which is a highly-active preparation of extract of liver B.P., extract of yeast, vitamin B₁ and nicotinic acid, provides the factors necessary for the maintenance of normal metabolic processes, and is thus indicated in all cases of nervous depression, reduced vitality, and lassitude or debility attributable to dietary deficiencies. It is issued in bottles of 4 and 16 fluid ounces, also in bottles of 80 fluid ounces for dispensing.

to pay £1,200 spread over only ten years, as well as 4% interest and a life insurance premium" (my italics). The correct figures are that for a loan of £1,000 the quarterly repayments amount to £30 9s. 1d., but these include repayment of both capital and interest at 4% and there is no further interest payable in addition. On this basis, the total amount paid over the whole period of ten years amounts to £1,218 3s. 4d., which is inclusive of all interest. I think it will be agreed that this presents the matter in quite a different light, and in my experience of medical practice loans, which is extensive, such terms have never before been obtainable.

One further point emerges, and it is that from Dr. Penny's letter it might be gathered that the life assurance premium is also substantial. In fact, assuming the applicant to be under 35 years of age and a first-class life, £1,000 life assurance for his specific purpose can be provided at a figure not exceeding £15 per annum per £1,000. This premium is also subject to tax relief at 3s. 6d. in the £, so that the resultant commitment can in no circumstances be considered excessive. Comparing these terms with those of pre-war days, and taking into account that it is now possible in approved cases to advance 100% of the purchase price (providing this does not exceed 1½ years' purchase calculated on the average of the past three years), I think it may be agreed that the terms offered are not unduly onerous.—I am, etc.,

Medical Insurance Agency,
London, W.C.1.

A. N. DIXON,
Manager.

SIR,—I have always been strongly opposed to the custom of buying and selling practices, and as was pointed out by Dr. Dan E. Davies (Jan. 10, p. 70), with whose letter I entirely agree, this opposition was shared by a large majority of the profession—at any rate as late as March, 1944. This custom was bad enough in the old days, when the cost of running a practice was considerably lower than it is to-day and income tax round about 2s. in the pound. A young man buying a practice then could by hard work and steady application possibly remove the millstone from his neck in four or five years—but what hope has he to-day, with the high cost of everything and income tax at 9s. in the pound?

I suggest to all young men hoping to enter private practice under the bad old custom to first do a little sum in arithmetic to find out how long they will have to struggle along, with a very small income, until they can finally remove the cramping fetters of debt. I think then they will appreciate the fact that it is better for their practice to be owned by the State than by some heartless moneylender, and by voting "Yes" at the plebiscite remove one of the biggest evils which has hampered the profession in past years.—I am, etc.,

Tonsyrell, Glam.

F. L. BREWER.

SIR,—Dr. W. Maxwell Penny (Jan. 10, p. 72) raises a point of the greatest importance. Unfortunately he quotes payment of £30 per quarter for ten years as repayment of capital only, when it is payment of interest as well on a loan of £1,000. But still this payment of interest and life-insurance premiums is too heavy a burden for younger practitioners without capital who are at all unlucky.

Can it not be clearly acknowledged that the split in the profession on which Mr. Bevan pins his hopes with his unprincipled bribes for blacklegs is between the prosperous doctors and those who have yet to prosper? And cannot this gap be bridged by a system of interest-free loans from the moneyed doctors to the moneyless? Such a scheme would indeed be worthy of the noble and learned profession that we claim to be.

As it is, the younger man without capital might be induced to think that his choice lies between servitude either to Mr. Bevan or to banks and insurance companies. If he nobly renounces this Minister's bribes and blandishments we certainly shall owe to him greater financial consideration than we ourselves enjoyed from our elder brethren in the past.—I am, etc.,

Ruislip, Middlesex.

WILLOUGHBY CLARK.

SIR,—One of the main arguments put forward by various protagonists of the National Health Act is that the young doctor will be saved the financial worry of buying a practice. On this assumption I was for a while a supporter, but now I am either "dim" or sadly disillusioned, for, however I view

the situation, I cannot see this advantage being gained by the young practitioner on joining the medical service on or after the appointed day. At the moment there are two main methods of joining in general practice. One either buys a practice, thereby ensuring an immediate income at the cost of a capital expenditure, or one puts up a "plate" in a suitable area and sits and waits.

This latter method is equally costly, as for the first two or three years a certain standard of living has to be maintained, to say nothing of buying the house. Under State medicine the new practitioner is left with only the latter method, with the slight advantage that when he has an as yet unspecified number of patients he'll be given the handsome basic salary of £300 a year. The idea of stepping into a ready-made practice for nothing is a myth for the great majority, as at the best it means waiting for a "dead man's shoes." It may be that I have not correctly interpreted the full details of the new Act, but I understand that at the present the Minister has no power to dictate to a patient as to which doctor he must attend.—I am, etc.,

London, N.2.

S. EDELMAN.

SIR,—Should we not do more to remove the mote from our own eye when we have removed the beam from that of the Minister?

I can still recall the anxious days and sleepless nights I spent fifteen years ago when, as an almost penniless assistant after five years, the death vacancy in the partnership threatened to elude me for the lack of £420. I was finally enabled to carry out what proved to be a satisfactory piece of business by the generosity of an unexpected guarantor and the farsightedness of a bank manager who did not insist on collateral security.

Surely the profession does not require outside assistance from either the Minister or commercial firms to ensure that no deserving young practitioner is precluded from purchasing his practice or share by lack of capital?

I suggest that when we have won our battle each owner of an established practice forthwith loans to a central fund one-twentieth of the value of his goodwill; he may with luck receive annual interest thereon at 2½%. The central fund would, after due safeguards, advance capital to prospective purchasers at 3½%, using the estimated profit for administrative expenses.

An alternative method might require a much smaller capital sum, non-interest-bearing, to form a non-collateral guarantee fund; such a fund would earn little interest for the medical lenders as this would be payable to such banks as allowed overdrafts to purchasers on the guarantee thereof. The figures are of course subject to auditor's adjustment and are based on the arbitrary assumption that at any given moment one in twenty of the then existing practices are in the process of being purchased.

Some such scheme would be of great benefit to both purchasers and vendors, and would eliminate one of the "sob-stuff" arguments used against the private ownership of goodwill.—I am, etc.,

Edlington, nr. Doncaster.

R. S. GILCHRIST.

Remuneration in the N.H.S.

SIR,—A matter which does not seem to have been discussed is the treatment in the N.H.S. of the older G.P. compared with the young novice. In private practice the man of ripe experience and judgment was able to command higher fees owing to his greater worth. Thereby he obviated to some extent the necessity of working himself to death by taking too many patients in order to support his family in their increasingly expensive upbringing and education, and to provide for old age. Often he was able to employ an assistant or son, a young strong man without responsibilities who could spare him much of the nightwork and other exacting duties, and who meanwhile was learning the art of general practice, perhaps to follow on as a partner.

Under the N.H.S., however, this will be quite changed. Assistants will be unobtainable except at excessive rates or pay. In order to gain the higher income which is due to him and often necessary the older man will have to take more patients—in fact, work harder than the young man with few patients. Furthermore, with the basic salary he will actually

get paid a smaller sum per patient than his less experienced colleague.

Example.—With 95% of the population on doctors' lists: The young man with only 1,000 patients will receive £1,058—i.e., £1 1s. 2d. per patient. The long-established man with 4,000 patients will receive £3,332—i.e., 16s. 8d. per patient.

Thus the older and presumably more experienced and reliable doctor will have to work four times as hard for only 10/13 the amount per service compared with the young doctor. Income tax will make the discrepancy even greater. This is a fine reward indeed for a man of 50 who has given his best to his patients for a quarter of a century, who knows their histories, family histories, and environments for a generation. His opinion is apparently not worth as much as that of a young colleague in his twenties of a couple of years' standing. This state of affairs is sure to sow discord at the present time. But maybe this will not be unwelcome to the Minister of Health. —I am, etc.,

Heanor, Notts.

J. W. O. HOLMES.

The Basic Salary

SIR,—Great stress is laid on the basic salary as being the first step to absolute control by the Minister of Health. The first step was taken in 1912 when we consented to serve under the National Health Insurance Act. We have only recently learned how to combine and fight against increasing duties and poor remuneration with considerable success. We have previously served under Ministers of all parties and none has been kind to us. I consider that the system in the Armed Forces, which gives increased pay for seniority, rank, and special qualifications, is preferable to capitation payment.

I agree with Dr. W. Edwards that it puts a premium on untutored youth and physical stamina and a discount on greying hairs and wise judgment. Surely the man with 1,000 or 2,000 actual patients on his books must give better individual attention than the one with 4,000 or 5,000. Under present conditions the doctor with smaller numbers will probably charge higher fees. If the bulk of his private list is to be brought in at contract rates he will suffer enormous loss. The 1944 questionnaire showed that general practitioners voted 12% in favour of a salary, 28% for a small basic salary and capitation, and 55% for capitation alone. One may fairly conclude that 40% favoured some salary and 55% no salary: 40% is a very considerable minority, which deserves full consideration.

As I am approaching the retiring age I wish to point out especially the injustice of the clause in the Act referring to the value of houses to be transferred to one's successor. My house is at a busy corner. Since I bought it in 1920 it has become mainly a built-up area, and I spent more than I paid in modernizing it. Surely I have the same right as any other owner to get the best price I can. My successor has the same right to accept or refuse my terms. The question of goodwill does not come into the matter; the house is a good centre for any doctor, but if some non-medical man thinks it worth more for another purpose I have surely a right to the best price I can get without interference. —I am, etc.,

Stockport.

C. HIBBERT.

Economic Persuasion

SIR,—I notice from recent correspondence that the Minister of Health considers the medical profession divided. Dr. Guy Dain denies this. I think we are almost unanimous in rejecting the N.H.S. Act as it now stands, particularly the section giving no right of appeal to the High Court. However, on the "appointed day" many of us will be compelled to join the new Health Service.

I am a young ex-Service doctor, a member of the B.M.A., 41 years qualified, and am struggling to keep my wife and family on £270 per annum in a junior resident hospital appointment. For over six months I have been searching in vain for a partnership in a country practice in the southern half of England, and judging from the B.M.J. advertisement columns I am many others in the same predicament. What representative body, professional or otherwise, would be able to advise members to be treated thus? Surely it is the more prosperous and senior members of the

B.M.A. gave a helping hand to the young ex-Service doctor; otherwise in July many of us will have no option but to join the Government Service.—I am, etc.,

Tavistock, Devon.

G. W. GIBBS.

Work the Act

SIR,—After reading carefully through the National Health Service Act, 1946, and the comments of Mr. A. Bevan addressed to the profession, together with the White Paper and the Negotiating Committee's report, I state quite freely that I like the Act. Mr. A. Bevan has kept the seven principles of the profession as published in the *Journal* of Dec. 15, 1945 (p. 833), well in mind, and he has watched with care the replies given to the British Institute of Public Opinion's questionnaire on the White Paper set out in the *Supplement* of Aug. 5, 1944 (p. 25), as shown by his following the lead of the profession in its desire for a basic salary and a capitation fee, but relying mostly on the capitation fee. There are no doubt ambiguities and legal perplexities in the Act, but what legal document has not got them? We are all human. But the main principles of the Act are sound and give the prospect of a good health service for the nation.

It is now for the profession to show its usual good will and forget the bickerings of the politicians and work the Act. Many doctors will ask, "What do my fellow colleagues think about it all?" To that question there has been a complete answer in the *Supplement* of Aug. 5, 1944, when 25,435 medical men and women answered the questionnaire on the medical service and the results were published. It would be well for all doctors to study those figures again, and it would be better for the B.M.A. to take a little more cognizance of those findings. The heads of our profession in the Presidents of our Royal Colleges of Physicians, Surgeons, and Obstetricians have set the example of seeking to co-operate with the Government. Let the general practitioner do the same and work the Act with all his accustomed good will and energy. I hope that all the 19,478 doctors (*Journal*, Jan. 11, 1947, p. 64) who were willing to negotiate with the Government will join the Service and give us a medical service worthy of our nation.—I am, etc.,

Croydon, Surrey.

C. I. STOCKLEY.

A Warning

SIR,—It appears to be widely supposed that any forecast of the condition of the profession under the National Health Service Act cannot be based on experience for the simple reason that no such Act has ever before been operated in this country. On the contrary, we have had for a century, in every town and hamlet of this country, a comprehensive medical service, administered by the Minister of Health, providing treatment and certification without charge, having hospital and general practitioner services. The practitioners are paid variously by salary, by capitation, and by attendance. Some of the practitioners do no other work; most, however, have other patients; some work at health centres provided by the local authority, others at their own premises. They have security of tenure of office "until they die or resign."¹ There is a superannuation scheme² in which some, but not all, participate.

In this letter I refer to the practitioner service, the District Medical Service of the Poor Law, a part of the Public Assistance Medical Service. It is so very similar to the practitioner service envisaged in the National Health Service Act that the new Act would, in fact, do little more than abolish the present income limit of patients and extend the principle of "free choice," thus increasing the number of patients and doctors in the service.

In other words the proposed "changes" are proposals for expansion of an existing service. The power and control of the Minister are fundamentally the same in this existing service as they will be after expansion. In case anyone should suppose that the Minister's concern with practitioners in the District Medical Service is remote I will quote the statute. The Minister is "charged with direction and control," may "define the duties . . . direct the mode of appointment and determine the continuance in office or dismissal . . . of District Medical Officers, and "regulate their salaries and the time and mode of payment thereof." The Minister of Health was until 1919 known as the President of the Local Government Board, and

earlier still, until 1871, as the President of the Poor Law Board. Let it not be thought that the Minister has any less statutory authority or responsibility in his first-begotten service than he has in the proposed new one.

Now the Minister, in the second paragraph of his address to the individual doctor,³ says that the latter "wants to know exactly where he stands" on simple questions. At almost the same date the Minister has told us where we D.M.O.s do stand.⁴ And this is where: (1) All appointments, including permanent superannuable appointments, are to be terminated. (2) There will be no compensation for loss of security of tenure and none for loss of superannuation rights. (3) The Minister refuses to hear representations on this matter.⁵ (4) The Minister's principal officers state that it is in accordance with "the general principles of compensation which are being adopted in current legislation—the principle that there should be no compensation in the case of part-time officers."⁶

As is well known, security of tenure and superannuation are, in all appointments, inducements to set against a lower rate of remuneration, and the rate of remuneration in the existing service (in my locality, at least) has gradually dwindled and is now less than half that of panel service. On this question of remuneration the Ministry refuse to hear representations.

It must be added that there are certain not very clear rights of transfer of credit for superannuation provided that the doctor serves under the National Health Service Act.⁷ In previous Acts, such as the Local Government Act, 1933,⁸ there have been appropriate and clearly defined provisions for compensation, so that if the holder of a permanent superannuable appointment could not continue in a similar capacity with continuing superannuation rights he would at least be compensated.

The Ministry, in declining to consider compensation, have suggested that where (as in most cases) we have other patients, we are "part-time," and imply that this "principle of current legislation" does not apply to "whole-time" officers. Whether it will extend to them in the future remains to be seen. I have worked for many years without imagining that it would ever apply to me. I give the facts but I offer no criticism. By Regulation I am not allowed to. For the same reason I must remain anonymous.—I am, etc.,

Tell the Public

SIR,—Is it not time that the British Medical Association, by means of the lay press, made the position quite clear to the public why it feels that the National Health Act, as it stands at the moment, is not satisfactory towards patient or doctor? I hear it so often expressed that doctors are against the Act because they will suffer financially, and it seems to be this that has produced a very strong feeling in the lay mind against the doctors at the present time. In fact I often hear it stated that doctors are already overpaid. Many laymen also feel that now they will obtain the services of a "London specialist" in the provincial hospitals, and that patients will be much more likely to be treated in their own locality, be it university town or small provincial or market town.

I suggest the following points need emphasizing: (1) That the argument over remuneration has been on a capitation basis in order to exclude slackers getting unearned pay. (2) The profession's view on the buying and selling of practices is in the patients' interest as well as the doctors'. (3) Section 35, being a very important issue, should be expounded and explained more fully to the public. (4) That control and regionalization will give the patient less liberty and choice over the doctor "specialist" who treats him and the locality of the hospital where he is to be treated. (5) The legal anomalies in the Act will lead to serious hardship to the public.—I am, etc.,

MARGARET DUDLEY-BROWN.

Greenhithe, Kent.

The Only Answer

SIR,—A few weeks ago I submitted an application for additional rations for one of my patients, suffering from inoperable gastric carcinoma. In due course I received a reply from the Ministry of Food stating that "the Medical Advisers regret that they are unable to recommend that the additional foods be supplied." We have seen numerous examples of this form of petty tyranny in recent months; the most odious aspect of which is the absolute callousness and disregard for individual human life, so entirely characteristic of the totalitarian system.

In the course of the last three years we have witnessed the spectacle of our liberties and individual rights being insidiously filched from us one by one; and I have not the slightest doubt that, if the National Health Service in its present form is inflicted upon us, we shall see yet further extensions of this form of control of our profession by our medical gauleiters. One of the primary objects of totalitarian States—so well exemplified by Nazi Germany and Communist Russia—is the absolute control of the learned professions, which, by virtue of their long-established traditions of liberty of thought and opinion, have always provided the nucleus of resistance to all forms of autocratic tyranny.

Surely the issue before us in the coming plebiscite is simple: it is not the merits or demerits of basic salary, capitation fees, or sale of goodwill; it is simply whether we want to live and work in a free country or a totalitarian slave-State. The history of the last ten years has shown conclusively the futility of attempting to "negotiate" with totalitarian systems, and that the answer, and the only answer, to tyranny is firm and unflinching resistance to the last. To our profession to-day belongs the honour of being the first line of resistance to the new despotism; let us therefore not fail, but stand together and return a united and uncompromising "No" in the approaching plebiscite.—I am, etc.,

Catford, London.

G. TAYLEUR STOCKINGS.

Whole-time Practitioners and the Act

SIR,—We have been surprised to hear the view expressed at recent meetings that the whole-time people do not matter, and that it appears to have been generally assumed that whole-time officers employed in hospitals will automatically accept service under the Act, because they do not find anything in it which conflicts with their principles. It is important that this misapprehension should be removed. Those of us who have chosen full-time service have done so voluntarily, and up to the present time have been happy to work in our respective fields with a full sense of professional freedom and independence. We have derived that independence from our ability to change our employing authority at will or in the last resort to transfer our allegiance solely to our patients and ourselves in the freedom of general practice.

We believe the broad intentions of the Act to be excellent and desirable, but the Minister's statement makes it abundantly clear that there is to be one employer and all are to be employed. To many of us who are at present engaged in whole-time service the Act may offer substantial material advantages, but it is vital that none of us shall ignore the fact that our freedom is essentially dependent upon a large body of general practitioners who shall not be paid by salary and who shall have the fundamental right of all men to appeal to a court of justice.—We are, etc.,

Support for the N.H.S.

SIR,—I have not yet noticed any letter in your columns supporting the Minister of Health's new Act in its present form, though I have no doubt that there are some doctors who take the view which I feel sure you are too courteous and impartial not to publish. I agree that Mr. Aneurin Bevan may well be planning a fully salaried State medical service as his ultimate

get paid a smaller sum per patient than his less experienced colleague.

Example.—With 95% of the population on doctors' lists: The young man with only 1,000 patients will receive £1,058—i.e., £1 1s. 2d. per patient. The long-established man with 4,000 patients will receive £3,332—i.e., 16s. 8d. per patient.

Thus the older and presumably more experienced and reliable doctor will have to work four times as hard for only 10/13 the amount per service compared with the young doctor. Income tax will make the discrepancy even greater. This is a fine reward indeed for a man of 50 who has given his best to his patients for a quarter of a century, who knows their histories, family histories, and environments for a generation. His opinion is apparently not worth as much as that of a young colleague in his twenties of a couple of years' standing. This state of affairs is sure to sow discord at the present time. But maybe this will not be unwelcome to the Minister of Health.—I am, etc.,

Heanor, Notts.

J. W. O. HOLMES.

The Basic Salary

SIR,—Great stress is laid on the basic salary as being the first step to absolute control by the Minister of Health. The first step was taken in 1912 when we consented to serve under the National Health Insurance Act. We have only recently learned how to combine and fight against increasing duties and poor remuneration with considerable success. We have previously served under Ministers of all parties and none has been kind to us. I consider that the system in the Armed Forces, which gives increased pay for seniority, rank, and special qualifications, is preferable to capitation payment.

I agree with Dr. W. Edwards, that it puts a premium on untutored youth and physical stamina and a discount on greying hairs and wise judgment. Surely the man with 1,000 or 2,000 actual patients on his books must give better individual attention than the one with 4,000 or 5,000. Under present conditions the doctor with smaller numbers will probably charge higher fees. If the bulk of his private list is to be brought in at contract rates he will suffer enormous loss. The 1944 questionnaire showed that general practitioners voted 12% in favour of a salary, 28% for a small basic salary and capitation, and 55% for capitation alone. One may fairly conclude that 40% favoured some salary and 55% no salary: 40% is a very considerable minority, which deserves full consideration.

As I am approaching the retiring age I wish to point out especially the injustice of the clause in the Act referring to the value of houses to be transferred to one's successor. My house is at a busy corner. Since I bought it in 1920 it has become mainly a built-up area, and I spent more than I paid in modernizing it. Surely I have the same right as any other owner to get the best price I can. My successor has the same right to accept or refuse my terms. The question of goodwill does not come into the matter; the house is a good centre for any doctor, but if some non-medical man thinks it worth more for another purpose I have surely a right to the best price I can get without interference.—I am, etc.,

Stockport.

C. HIBBERT.

Economic Persuasion

SIR,—I notice from recent correspondence that the Minister of Health considers the medical profession divided. Dr. Guy Dain denies this. I think we are almost unanimous in rejecting the N.H.S. Act as it now stands, particularly the section giving no right of appeal to the High Court. However, on the "appointed day" many of us will be compelled to join the new Health Service.

I am a young ex-Service doctor, a member of the B.M.A., 5½ years qualified, and am struggling to keep my wife and family on £270 per annum in a junior resident hospital appointment. For over six months I have been searching in vain for an assistantship in a country practice in the southern half of England, and judging from the *B.M.J.* advertisement columns there are many others in the same predicament. What other representative body, professional or otherwise, would allow its younger members to be treated thus? Surely it is high time the more prosperous and senior members of the

B.M.A. gave a helping hand to the young ex-Service doctor: otherwise in July many of us will have no option but to join the Government Service.—I am, etc.,

Tavistock, Devon.

G. W. GIBBS.

Work the Act

SIR,—After reading carefully through the National Health Service Act, 1946, and the comments of Mr. A. Bevan addressed to the profession, together with the White Paper and the Negotiating Committee's report, I state quite freely that I like the Act. Mr. A. Bevan has kept the seven principles of the profession as published in the *Journal* of Dec. 15, 1945 (p. 833), well in mind, and he has watched with care the replies given to the British Institute of Public Opinion's questionnaire on the White Paper set out in the *Supplement* of Aug. 5, 1944 (p. 25), as shown by his following the lead of the profession in its desire for a basic salary and a capitation fee, but relying mostly on the capitation fee. There are no doubt ambiguities and legal perplexities in the Act, but what legal document has not got them? We are all human. But the main principles of the Act are sound and give the prospect of a good health service for the nation.

It is now for the profession to show its usual good will and forget the bickerings of the politicians and work the Act. Many doctors will ask, "What do my fellow colleagues think about it all?" To that question there has been a complete answer in the *Supplement* of Aug. 5, 1944, when 25,435 medical men and women answered the questionnaire on the medical service and the results were published. It would be well for all doctors to study those figures again, and it would be better for the B.M.A. to take a little more cognizance of those findings. The heads of our profession in the Presidents of our Royal Colleges of Physicians, Surgeons, and Obstetricians have set the example of seeking to co-operate with the Government. Let the general practitioner do the same and work the Act with all his accustomed good will and energy. I hope that all the 19,478 doctors (*Journal*, Jan. 11, 1947, p. 64) who were willing to negotiate with the Government will join the Service and give us a medical service worthy of our nation.—I am, etc.,

Croydon, Surrey.

C. I. STOCKLEY.

A Warning

SIR,—It appears to be widely supposed that any forecast of the condition of the profession under the National Health Service Act cannot be based on experience for the simple reason that no such Act has ever before been operated in this country. On the contrary, we have had for a century, in every town and hamlet of this country, a comprehensive medical service, administered by the Minister of Health, providing treatment and certification without charge, having hospital and general practitioner services. The practitioners are paid variously by salary, by capitation, and by attendance. Some of the practitioners do no other work; most, however, have other patients; some work at health centres provided by the local authority, others at their own premises. They have security of tenure of office "until they die or resign." There is a superannuation scheme in which some, but not all, participate.

In this letter I refer to the practitioner service, the District Medical Service of the Poor Law, a part of the Public Assistance Medical Service. It is so very similar to the practitioner service envisaged in the National Health Service Act that the new Act would, in fact, do little more than abolish the present income limit of patients and extend the principle of "free choice," thus increasing the number of patients and doctors in the service.

In other words the proposed "changes" are proposals for expansion of an existing service. The power and control of the Minister are fundamentally the same in this existing service as they will be after expansion. In case anyone should suppose that the Minister's concern with practitioners in the District Medical Service is remote I will quote the statute. The Minister is "charged with direction and control," may "define the duties . . . direct the mode of appointment and determine the continuance in office or dismissal . . ." of District Medical Officers, and "regulate their salaries and the time and mode of payment thereof." The Minister of Health was until 1919 known as the President of the Local Government Board, and

earlier still, until 1871, as the President of the Poor Law Board. Let it not be thought that the Minister has any less statutory authority or responsibility in his first-begotten service than he has in the proposed new one.

Now the Minister, in the second paragraph of his address to the individual doctor,⁵ says that the latter "wants to know exactly where he stands" on simple questions. At almost the same date the Minister has told us where we D.M.O.s do stand.⁶ And this is where: (1) All appointments, including permanent superannuable appointments, are to be terminated. (2) There will be no compensation for loss of security of tenure and none for loss of superannuation rights. (3) The Minister refuses to hear representations on this matter.⁷ (4) The Minister's principal officers state that it is in accordance with "the general principles of compensation which are being adopted in current legislation—the principle that there should be no compensation in the case of part-time officers."⁸

As is well known, security of tenure and superannuation are, in all appointments, inducements to set against a lower rate of remuneration, and the rate of remuneration in the existing service (in my locality, at least) has gradually dwindled and is now less than half that of panel service. On this question of remuneration the Ministry refuse to hear representations.

It must be added that there are certain not very clear rights of transfer of credit for superannuation provided that the doctor serves under the National Health Service Act.⁹ In previous Acts, such as the Local Government Act, 1933,¹⁰ there have been appropriate and clearly defined provisions for compensation, so that if the holder of a permanent superannuable appointment could not continue in a similar capacity with continuing superannuation rights he would at least be compensated.

The Ministry, in declining to consider compensation, have suggested that where (as in most cases) we have other patients, we are "part-time," and imply that this "principle of current legislation" does not apply to "whole-time" officers. Whether it will extend to them in the future remains to be seen. I have worked for many years without imagining that it would ever apply to me. I give the facts but I offer no criticism. By Regulation I am not allowed to. For the same reason I must remain anonymous.—I am, etc.,

Support for the N.H.S.

SIR,—I have not yet noticed any letter in your columns supporting the Minister of Health's new Act in its present form, though I have no doubt that there are some doctors who take the view which I feel sure you are too courteous and impartial not to publish. I agree that Mr. Aneurin Bevan may well be planning a fully salaried State medical service as his ultimate

objective. If this be so, I see no reason why the public should not derive at least as satisfactory service as they do from the public health departments, the Naval, Military, and R.A.F. medical services during the war, the E.M.S., or the "panel." Although our Civil Service is much decried by us it is a model to all others throughout the world. There is no institution that I know of which has not the faults (and the advantages) of its inherent structure.—I am, etc.,

London, W.3.

RONALD LIVINGSTON.

State Servants

SIR,—During the course of conversation with many general practitioners I have found that almost without exception they are opposed to participation in the new Act. The main reasons are: (1) The insidious danger of becoming eventually full salaried servants of the State, with a certain duty to Whitehall. (2) That they are, from the word "go," potential Civil Servants, at the whim and fancy of one Minister whose views and record are only too well known. But they want reassurance concerning the "compensation" clause. Trying to avoid the money issue about which so much has been written, and which can be so unimportant, they cannot but be concerned that if they do not join on the appointed day they will lose all right to eventual compensation.

If we can firmly stipulate that we are not going to part with a very ancient and sound tradition—namely, the buying and selling of practices—we shall convince the Minister, and more important still our patients, that we are not parting with our goodwill; which is, after all, only a sound business proposition, saving for our dependants and our retirement.

The "mess of pottage" will surely be ours if we sacrifice ethics for financial worries.—I am, etc.,

Gloucester.

J. B. W. HAYWARD.

No Confidence in Minister

SIR,—Mr. Bevan has shown himself incapable of negotiation, or even of being polite to our committee; and his remarks and threats of a sharply reduced capitation fee "if there is much more quibbling" should convince even the most ardent young supporters of his scheme that their future and ours, when once we have signed on the dotted line, would be very uncertain financially. Apart from that, we don't like to think of medical officers of health being classified as "spivs" and "drones"; and the question of compensation is so vague that no confidence can be placed in the Minister or his Act as it stands.

We have only one course open, and that is to give our Negotiating Committee a 95% "No" in the forthcoming plebiscite. As Mr. Bevan is unwilling to negotiate there will be no point in attempting to deal with him further, and a demand for his resignation would only be in line with his own statement made in the House last year that he would "stand or fall by the Act." Our personal freedom and our patients' welfare must come first.—I am, etc.,

Appleby Magna, Burton-on-Trent.

J. R. SALMOND.

Will of the People

SIR,—Despite the numerical strength and the fervour of opponents of the Act, close perusal of your columns has failed to reveal a single valid argument to refute the view that "to oppose the Act is to oppose the will of the people as expressed through Parliament," as you succinctly put it (Jan. 10, p. 53). The only moral principle at issue is, Are we morally justified in insisting on a Conservative type of medical service in a State governed by a Parliament committed to the putting into effect of Socialist principles? Conservative, B.M.A. principles—private ownership and practice—like Socialist governmental principles—public ownership and practice—are merely political, and no moral issue is involved whichever side we take.

Who pays the piper calls the tune. Our patients pay us, and they should be allowed to call the type of medical service they want. We seek to impose on them the type we want and put ourselves gravely in the wrong.

I can admire the honesty of Dr. Dan E. Davies when he writes, "What we are really studying is our own interest, first, last, and always" (Jan. 10, p. 70). We ought, of course, to be

studying first, last, and always what type of medical service will best serve the health of the people. The patient's interests must come first; we exist merely to serve him.—I am, etc.,

Wallasey, Cheshire.

LENNOX JOHNSTON.

** Dr. Johnston should have given the full quotation. We said was this: "Some medical men have argued that oppose the Act is to oppose the will of the people as expressed through Parliament. But as Dr. Hill put it in his speech last week: 'The Minister has told us of our right as individuals and our right collectively to determine our attitude to the Service. We are within our rights in saying No.'"—Ed., B.M.

Refusal

SIR,—I refuse to enter the National Health Service unless the Act is amended. I am under 40, have no other training, have family to support, and cannot live without working as a doctor. I have also left the area where I could have counted on a good following. If those members of the B.M.A. who have accepted seats on boards, etc., cannot see their way to follow, will they at least resign from a scheme they know to be wrong?—I am, etc.,

Newquay, Cornwall.

J. P. O'SHEA

"Free Choice"

SIR,—The Minister of Health has taken great pains to stir the "free choice" of the individual doctor to join or not join the National Health Service. It would be of interest to what the Minister understands by a "free choice." For example, the value of an individual practice may be between figures £1,000 and £7,000. Thus if on the appointed day doctor exerts this so-called "free choice" and contracts out the Service, he will lose this asset, since he is no longer permitted to sell his practice. If he does sign, however, he will be compensated, perhaps equally, perhaps not. The larger individual doctor's practice the greater the financial loss should he decide not to join the new Service.

In any other circles but the Minister's, a choice between two courses—one involving heavy financial loss and the other loss but perhaps even a slight gain—would be considered rather an unusual interpretation if described as free. The doctor feels, might be forgiven if he thought a little pressure was being put on him to take a certain line of action. He might in fact even feel he was being bribed.—I am, etc.,

Brighton.

S. L. KAYE

National Health Service

SIR,—As an active and lifelong Conservative I never thought I should find myself in agreement with a left-wing Socialist periodical, but I am bound to say that the *Tribune's* reference to us as a reactionary profession very adequately describes the bulk of the correspondence in your last two numbers.

If we can find no stronger grounds upon which to fight the Socialist Minister of Health than direction, which does not exist, or anyway which is unchanged, than the retention of the right to buy and sell practices, already agreed upon by the profession as undesirable in the 1944 plebiscite, and by opposition to payment by part-salary, upon which in the same plebiscite the profession was almost equally divided, then we are lost indeed.

Is it seriously suggested, except for propaganda, that we have ever been able to practise where we want to? If it is, let whoever thinks so go and try. After the war I wanted to practise in Sussex. The only country practice that came into the market then had seventy applicants. We all obviously wanted to practise there. Could we? For heaven's sake let us drop this nonsense.

With regard to the sale of practices, is it fully realized that with interest and taxation at its present rate it is impossible for a young man without capital to borrow money to buy his practice, maintain a decent standard of life, and at the same time provide for himself and his family after retirement? The assured income, pension, and widow's pension in the Health Act must be a real ray of hope to many young doctors, and these are the people who should be considered. Also to think it reasonable that one should be able to buy oneself into a comprehensive service is just as absurd as to think one should

TRADE MARK

'SULPHATRIAD'

BRAND

compound sulphonamide tablets

'SULPHATRIAD' contains, in each tablet:

sulphathiazole	0.185 gramme
sulphadiazine	0.185 gramme
sulphamerazine	0.130 gramme

We are pleased to announce that supplies of 'SULPHATRIAD' are now available through the usual trade channels.

'SULPHATRIAD' is suggested in the treatment of acute infections due to pneumococci, gonococci, meningococci, β -haemolytic streptococci, *Bact. coll.*, *H. ducreyi* and in gas gangrene. It may also be used as an adjuvant to penicillin therapy in grave *S. aureus* infections and in the treatment of localised staphylococcal infections such as boils, carbuncles and whitlows.

Since the solubility in the urine of each of the constituents of 'SULPHATRIAD' is not affected by the presence of the other two, the risk of renal complications such as crystalluria during treatment with this combination of sulphonamides is greatly reduced. Such a combination may also have certain advantages from the point of view of therapeutic activity.

Ortho-Gynol

VAGINAL JELLY

for effective conception control

Reliability of contraceptive action . . . freedom from irritation . . . and fine aesthetic qualities have made Ortho-Gynol a universally prescribed contraceptive preparation.

Ortho-Gynol is instantaneously spermicidal. It has a buffered acidity to conform to the normal vaginal pH—is readily miscible with

vaginal secretions and semen—and is safe to use over long periods because of uniform stability and freedom from irritation. Ortho-Gynol is available with or without the Ortho measured-dose applicator.

Active ingredients: Ricinoleic acid 0.7% w.w., boric acid 3.0% w.w. and oxyquinoline sulphate 0.025% w.w.

For maximum control, Ortho-Gynol is usually prescribed in conjunction with a vaginal diaphragm.

The HECSON

SUPER ELASTIC TRUSS
for the Treatment of Hernia

Strap is fixed to Pad at A. Therefore greater pressure is exerted at B, when the strap is pulled tightly.

Where treatment of Hernia by surgical methods is undesirable for any reasons, the HECSON super elastic truss can be confidently recommended. The Special Feature of the HECSON Truss is that the perineal or under strap is attached to the top of the pad instead of the lower margin as in the ordinary elastic or old spring truss. Thus it becomes part of the leverage mechanism for increasing the pressure of the pad at its base.

Price: Single £2 12s. 6d.
Double £3 13s. 6d.

still be able to buy a commission in the Army, and I am sure that the latter practice only died after a hard fight from the reactionaries of that time!

And now as to the salary. It is freely stated that the inclusion of a basic salary is the prelude to a whole-time salary within two years. (Incidentally, I believe, the original policy of the Conservatives.) Is this pure conjecture, or is there any inside information that we lack? If there is positive information on this point, let's have it and I'll believe it.

We are getting our usual indifferent Press. *The Times* advises us to drop our opposition to the question of the sale of practices, the *Sunday Times* to concentrate on getting the right of appeal to the courts—and there's the really important thing, the only one that matters. Let us concentrate on this, and also get the question of partnerships cleared up, and we shall be all right.—I am, etc.,

Stradbroke, Norfolk.

J. V. DOCKRAY.

A Sign of Carcinoma

SIR,—I am indebted to Mr. A. Dickson Wright for drawing attention to the value of the diagnostic manœuvre which he described and portrayed in the *Journal* of Jan. 3 (p. 27). But first we must insist that the preliminary examination of breast cases should be made with the patient stripped to the waist and standing. It is only in this position that the breasts are really dependent and that the signs of the presence of malignant disease due to general retraction are most likely to be observed. These signs are diminution of the size of the organ with elevation or deviation of the nipple, and, however slight, they are most significant. It is as a corollary to this examination with the patient standing that I conceive the arms above the head position may be useful.

But the breast must also be examined with the patient recumbent. It is an additional aid in the examination of the axilla, and especially in stout people, to get the patient to lie on the side with the suspected organ uppermost. In this position the contents of the axilla are dragged forwards by the weight of the breast, and quite often enlarged nodes, not previously detected, may be easily palpated or even seen.

Of course there are many other points useful in diagnosis, but if, when all the aids have been employed, there is still real doubt, then direct exploration is justified. In making this statement I am well aware of the hornets' nest I may be disturbing. It was my former colleague, Mr. A. K. Henery, who taught me that an incision down to, but not into, a doubtful lump may settle the question of its nature, the curious drawing in and fixation of the fat around a malignant neoplasm being characteristic. If, with this restraint, the surgeon still has doubt, he can deepen the cut to obtain the information which may be so valuable in the interest of the patient. To arrive at an accurate and complete diagnosis in doubtful breast cases we need to take much care and not grudge the time spent in investigation. I have heard it said that Halsted sometimes took nearly an hour over the complete examination of a difficult breast problem.—I am, etc.,

Taplow, Bucks.

G. GREY TURNER.

Cancer of the Lung

SIR,—I was interested to see in your account of the annual report of the British Empire Cancer Campaign (Jan. 3, p. 22) the suggestion that the increase in the incidence of cancer of the lung (16.5 times in men, 8 times in women) between 1921 and 1938 might be connected with the doubling of the consumption of tobacco in this period. I have often wondered if tobacco smoke had anything to do with carcinoma of the lung, but I think that the mere statement that smoking has increased misses an important point. When I was a young man pipe-smoking was the main form of the pleasure or vice, as one may look at it; cigarettes were "used when one was not smoking," as I think the author of the *Wind in the Willows* said. Few people inhaled, and I cannot remember seeing a case of primary cancer of the lung when, early in the century, I was a student. Somewhere about the time of the first world war pipes fell rather out of fashion and cigarettes came to the fore. Most cigarette-smokers inhaled—they could not get much fun out of it otherwise—and cancer of the lung began to be more common. This may be a mere coincidence, for I do not know

if the tar in tobacco smoke contains a carcinogenous element. I have also heard it suggested that the inhalation of the dust from tarred roads, also more or less corresponding in date, might be a factor. Perhaps both are. But even if inhaling cigarette smoke is proved to be a cause of carcinoma I doubt if people will give it up.—I am, etc.,

Guildford, Surrey.

E. W. SHEAF.

Simple Test for Pulmonary Tuberculosis

SIR,—This is a plea for the use in general practice of a very simple test by which to estimate progress in cases of pulmonary tuberculosis. Britton and Whitby say that the normal average of monocyte to lymphocyte is 1 to 3; that Sabin and his colleagues found that in cases of pulmonary tuberculosis 1 to any number less than 3 suggested possible activity, and 1 to 1 or any number less than 1 was a bad prognostic sign. I had a simpler suggestion from Heap in England more than 30 years ago and have found it of immense value in connexion with the sedimentation rate and x-ray findings. I have not yet found a case of unfavourably advancing pulmonary tuberculosis without a ratio of 1 to 1 or less than 1; nor in controls without pulmonary tuberculosis has the blood picture been anything like it.

It has even an advantage over the high sedimentation rate in that (1) there is no need to correct for anaemia; (2) there are comparatively few conditions giving a blood picture of high monocyte-lymphocyte ratio—glandular fever, an early stage at commencement of measles—while there are many that produce a high E.S.R. Thus it may help in differential diagnosis. I had two patients illustrating this. A mongol with a swinging temperature 101°–97° F. (38.3°–36.1° C.) for two months, cough, and wasting, and E.S.R. 150. Clinically it seemed obviously a case of pulmonary tuberculosis. His blood picture never gave a high monocyte-lymphocyte ratio: a week before his death it was 1 to 5. At necropsy it was found to be bronchial cancer, and no evidence at all of tuberculosis. The second was a man of 70 who suffered for years from chronic bronchitis. Tuberculosis was not suspected, until on one routine examination of his blood I found a 1 to 1 monocyte-lymphocyte ratio. X-ray examination and the presence of tuberculous bacilli in his sputum confirmed the diagnosis.—I am, etc.,

London, W.C.

H. ANGELL LANE.

B.C.G. in Control of Tuberculosis

SIR,—In his paper on B.C.G. (Nov. 29, 1947, p. 855) Prof. G. S. Wilson submits some of the published reports to a criticism which, as your leading article suggests, is rather exacting, having regard to the conditions under which the evidence must be obtained. But he is more tolerant towards Levine and Sackett's report of the New York results, which purports to show B.C.G. as ineffective. Had he applied to this analysis the same standard of criticism which he applied to the more favourable results of Rosenthal, Bland, and Leslie,² he would have made more than casual reference to the gross fallacy which the former contains, a fallacy which should exclude it from serious consideration but which is neglected by those who use the results to support their own argument. The whole New York investigation, of course, has little bearing on the efficacy of B.C.G., since it neglects the principle of avoiding infection before immunity has been established. But there is a much more serious error in the statistical analysis which, if corrected would leave the results showing almost the maximum possible difference in favour of B.C.G., though even that would have only a limited significance.

During the total period of 20 years deaths from tuberculosis among vaccinated children were 11, of which 8 occurred during the period 1933–46, to which importance is attached because selection was then automatic. During this latter period the death rate among vaccinated and controls was almost the same. But of the total 11 deaths, 10 occurred in infants known to have been exposed to positive-sputum contact in the home prior to vaccination. No claim has been made that B.C.G. immunization could check an infection already established, and individuals for whom that possibility exists must be excluded from analysis. In some analyses all those exposed before allergy appears are excluded. If, however, the 10 deaths where previous exposure was known are excluded, there is left 1 death

in the vaccinated group (period not stated). The difference in favour of B.C.G. is almost the maximum possible, but for the period of automatic selection even that maximum is less than three times its standard error. As a matter of fact, the data given suggest that some of the vaccinated who died were really infected after vaccination, but the probability is not one which can be admitted in selection of statistical material. The correct verdict on Levine and Sackett's analysis is that it has, at best, doubtful significance, but that what admissible evidence it presents is in favour of B.C.G.—I am, etc.,

Cardiff.

SIR,—Dr. W. E. Snell's letter (Dec. 20, 1947, p. 1007) prompts us to state that nothing has arisen in connexion with B.C.G. during the last three years to cause some of us to change the opinion that we formed of it twenty years ago. Propaganda has reached such proportions in this matter that even those like Dr. Snell who knew of the excellent work with B.C.G. in Oslo, and those who are now learning of it for the first time, are perhaps arriving at wrong conclusions.

Among other matters Dr. Snell states: "I was glad to read in your leading article that tuberculin-negative nurses certainly need protection, a point I endeavoured to make in your correspondence columns some three years ago. Unfortunately, some of our leading tuberculosis workers still await conversion to this belief." While disclaiming the title of "leading tuberculosis workers," we did take part in that correspondence, in which we insisted that tuberculin-negative nurses, like all hospital workers, need protection. But it is yet to be proved that B.C.G. gives the protection that is needed; for those who use B.C.G. in tuberculin-negative nurses still get cases of tuberculosis in these girls. Therefore the strictest medical supervision, healthy living conditions, and proper measures to reduce the risk of infection are still necessary and should be enforced at once—even if B.C.G. is to be given a trial, or even if a better vaccine becomes available.—We are, etc.,

A. CLARK PENMAN.

Market Drayton, Salop.

Diagnosis of Poliomyelitis

SIR,—I am surprised that in the many recent articles published on poliomyelitis no mention has been made of the value of repeating lumbar puncture in establishing the diagnosis in this disease. The frequent occurrence of a late rise in the protein content of the C.S.F. as well as the dissociation between the protein content and the cell count has been previously observed. These facts can sometimes be utilized in clinching a doubtful diagnosis, as illustrated by the following five cases, selected from a total of 53 cases which were under my care at Claydon Isolation Hospital during the recent epidemic.

Case 1.—A boy aged 14 years was admitted on Aug. 8, 1947, with a history of lumbar pain and weakness of the legs, commencing on the previous day. Pyrexia and signs of meningeal irritation were present. C.S.F. examinations gave the following results: Aug. 8, 1947, 4 cells per c.mm. and 20 mg. of protein per 100 ml. Aug. 22, 87 cells per c.mm. and 75 mg. of protein per 100 ml. During the interval between the above examinations the patient suffered from remittent pyrexia and stiffness of the back. No definite paralysis could be established and recovery appeared to be complete.

Case 2.—A woman aged 20 years was admitted on Sept. 15, 1947, with a history of weakness of the right hand since Sept. 7. The signs present on admission were entirely paralytic and practically confined to the right forearm extensors—an unusual distribution in poliomyelitis. Other causes of wrist-drop had to be considered. Result of C.S.F. examinations: Sept. 15, 8 cells per c.mm.; 30 mg. of protein per 100 ml. Oct. 9, 8 cells per c.mm.; 40 mg. of protein per 100 ml.

Case 3.—A boy aged 12 years. The disease commenced with headache on Sept. 13, 1947, and the patient was admitted on Sept. 17 showing signs of meningeal irritation. Result of C.S.F. examinations: Sept. 18, 10 cells per c.mm.; 35 mg. of protein per 100 ml. Oct. 3, 22 cells per c.mm.; 50 mg. of protein per 100 ml. This was a purely meningeal case showing no evidence of paralysis at any stage.

Case 4.—A man aged 40 years. The illness commenced on Sept. 16, 1947, with pain in the arms, legs, and neck. The patient was admitted on Sept. 22 with general muscular weakness. This was widespread but mostly incomplete paralysis involving

in a rather symmetrical fashion all four limbs and trunk. Partial respiratory paralysis necessitated four weeks' continuous treatment in a respirator, during the greater part of which time he suffered from marked mental abnormality. A workmate engaged in paint-spraying was treated for paralysis at another hospital, where a neurologist suspected lead poisoning. Result of C.S.F. examinations: Sept. 23, 3 cells per c.mm.; protein, 30 mg. per 100 ml. Oct. 21, 1 cell per c.mm.; protein, 40 mg. per 100 ml.

Case 5.—A boy aged 17 years. The illness commenced with stiffness of the neck on Oct. 12, 1947, and he was admitted on Oct. 17. On admission there was pain and weakness in the neighbourhood of the right shoulder and hip, and left wrist and ankle. It was thought that the affected ankle had a slightly puffy appearance, and the erythrocyte sedimentation rate was 50 and 70 mm. after one and two hours respectively. A rheumatic condition was suspected. Result of C.S.F. examinations: Oct. 18, 1 cell per c.mm.; 30 mg. of protein per 100 ml. Oct. 28, 22 cells per c.mm.; 45 mg. of protein per 100 ml. The second result weighted the diagnosis in favour of poliomyelitis.

Though it is possible that in some cases the C.S.F. remains normal throughout the course of the disease, I believe that many of the normal findings depend on the particular phase of the disease during which lumbar puncture has been performed. I am indebted to the staff of the Pathological Laboratory, Churchfield Road, Ealing, for the examination of the cerebrospinal fluids.—I am, etc.,

Croydon.

J. J. LINEHAN.

Measles Prophylactic

SIR,—Dr. Harwood Stevenson (Dec. 6, 1947, p. 928) and Dr. A. H. Morley (Dec. 27, 1947, p. 1054) have both advocated the use of parental whole blood as a routine in the attenuation of measles in contacts. There is, however, a danger which should be taken into account before advocating this procedure as a routine. I refer of course to the possibility of sensitizing the recipient of the blood to the Rhesus agglutinin. It is now accepted^{1,2} that the intramuscular injection of Rhesus-positive blood into a Rhesus-negative individual may result in the sensitization of the recipient, which, although giving rise to no ill-effects at the time of injection, may do so at a later period, so that in the case of females a "Rhesus-positive pregnancy" may result in iso-immunization and its sequelae.

There is no such danger attached to the use of adult serum, the use of which I should advocate until a satisfactory gamma-globulin fraction is produced in sufficient quantities in this country.—I am, etc.,

T. S. MARSHALL,
Regional Transfusion Centre

Leeds.

Herpes Zoster

SIR,—In view of the recent publication of cases of herpes zoster showing unusual clinical manifestations we wish to record the following case which appears to be similar to Case 3 reported by Dr. Thomas Parkinson (Jan. 3, p. 8).

A man aged 63 was admitted on Dec. 16, 1947, from a neighbouring hospital with a diagnosis of erysipelas and ulcerative stomatitis. For the previous two weeks he had experienced pain in the right ear, buzzing noises in the head, and severe headache, which had prevented sleep for the two days prior to admission. For a week his throat had been sore and there had been ulcers on the gums and tongue, causing difficulty in swallowing solids. The right side of the face became inflamed on Dec. 13. There was no previous history of chicken-pox or herpes zoster, nor any contact with these two conditions.

On examination he was a plethoric man with swelling of the right side of his face, particularly affecting the lips, cheek, temple, and submaxillary region. There was a well-marked erythema over this area, with typical zoster vesiculation and crusting. There were no vesicles in the external auditory meatus. On the right side of the tongue there were circumscribed areas of shallow ulceration, and two or three smaller areas were present on the inner side of the cheek and the hard palate on the same side. The temperature was 98.8° F. (37.1° C.). No further spread of the lesions occurred and the pain subsided slightly, although oedema of the submaxillary region with lymphadenitis became very marked owing to infection of the lesions of the chin. This was treated with 40 g. of sulphathiazole and 3 mega units of penicillin, and by Dec. 23 the mouth lesions and infected areas had healed, except for a small ulcer on the tongue and a patch of eczema on the chin. This latter area

was noticed to be continually moist owing to saliva dribbling out of the right corner of the mouth, particularly at night. On Dec. 30 a definite right facial palsy became apparent, and at the same time intense neuralgic pains occurred in the area of the face which had previously been affected by herpes. The paralysis became absolute in both upper and lower facial areas, and although there was no sensory loss over the face the neuralgia and feeling of numbness persisted and spread up into the right side of the temporal region over the right eye. There was no alteration in taste, but there was a diminution in the acuity of hearing in the right ear. The patient was discharged on Jan. 8 to attend as an out-patient for physiotherapy.

—We are, etc.,

Newcastle-upon-Tyne.

E. G. BREWIS.
C. NEUBAUER.

SIR,—I read Dr. Thomas Parkinson's article on herpes zoster (Jan. 3, p. 8) with great interest, and I feel it opportune to quote briefly two cases which occurred about a year ago in this practice.

Case 1.—A man of 34 came to see me complaining of dysuria and pain in his left side. The urinary symptom was one of precipitant micturition and was of two days' standing. His background showed that he was in the midst of divorce proceedings, and I decided the symptoms were functional in origin. I gave him an appointment to come and see me at a later date to take a fuller psychiatric history, but he returned the next day with a herpes rash in the line of the 3rd lumbar nerve. A few days later his urinary symptoms cleared and the herpes rash ran its usual course. I told my partner about this man and he quoted the following case to me which he had seen about the same time.

Case 2.—Dr. W. J. Meldrum was called in to see a man of 75 who had all the symptoms of a subacute intestinal obstruction. His abdomen was distended and he looked very ill. Rectal examination revealed hard masses of faeces, which were digitally removed. Before leaving, the patient complained of a pain in his left side, but in view of the more obvious obstructive symptoms it was not considered of any great significance. The next day the old man had a herpes zoster rash where previously he had had pain. Neither before nor since has he had such difficulty with his bowels, and it is suggestive that the herpes lesion had caused intestinal atony.

I mention these two cases because Dr. Parkinson makes no mention of the autonomic nervous system in his paper. If two such cases can occur in one practice, it is obvious that similar zoster symptoms must be relatively common, but they usually pass unnoticed.—I am, etc.,

Ibstock, Leicester.

C. A. H. WATTS.

Relief of Pain in Midwifery

SIR,—It is indeed surprising that so little attention is given to the problem of analgesia in labour. Anaesthetics are many, and useful in their sphere, but methods of analgesia (complete or partial relief of pain in the wear and tear of labour) are few. At the best, they would appear to be confined to verbal adjurations such as: "Bear down," "Don't hold your breath," "I should give her a sniff, now," "See you later, when it's ready," "I'll give you something"; "Nurse will see to it"—with perhaps "an injection" or "a tablet." I believe that the worry of labour can be lessened for everyone—for, although the woman is the main sufferer, the attending doctor and nurse must also participate to a greater or lesser degree if they are "midwifery conscious." I am of the firm belief that midwifery should be done by a team, not necessarily composed of experts, but of experienced practitioners who have the welfare of midwifery at heart and who are supported by nurses of similar persuasion. They would assume complete responsibility for antenatal care, conduct of labour and delivery, thus inspiring in the woman a confidence in her outlook which in the present state of affairs is certainly not engendered.

As invaluable and proved adjuvants I would suggest the resuscitation of two aids, both simple and safe, which provide relief from pain, sleep, and a degree of oblivion. The reason these have fallen into disuse appears to be only that they involve a little trouble for everyone but the woman. I refer to, first, Dr. David R. Jennings's hyoscine amnesia in labour (*B.M.J.*, 1929, 2, 801), and, secondly, Minnitt's gas-air analgesia. Briefly, Jennings's treatment is similar to "twilight sleep" but no morphine is used, resulting in a feeling of well-being in the woman during and after labour and a notable absence of somnolence in the child. In regard to

Minnitt's apparatus, suffice it to say that in his observations Dr. Minnitt has conscientiously recorded the causes of failure to relieve pain, the main one being lack of co-operation. Sad to say, this may occasionally be the woman's fault, but much more often is failure to relieve pain owing to the complete lack of sympathy for the woman and understanding of the apparatus by the attendant—doctor or nurse. Dr. Jennings and Dr. Minnitt have rendered signal service to midwifery which has yet to be fully appreciated, while Dr. John Elam, of New Barnet Hospital, has spent many years in careful observation of gas-air analgesia, with very favourable findings. To these voices crying in the wilderness I would add mine and say, "Tell the women!"—I am, etc.,

Dundee.

C. A. ALLAN.

Drug Addiction

SIR,—It is a sad but true fact that morphine addiction is incurable, notwithstanding all evidence to the contrary. Relapses after extensive treatment appear to be inevitable and necessitate constant supervision, combined with periods of hospital treatment from which the addict gains little and suffers greatly. When, in other branches of medicine, an incurable condition is encountered, all available knowledge is used to alleviate suffering. Treatment in such cases does not consist in giving repeated therapy which hurts but does not help.

The morphine addict after a time ceases to gain pleasure from the drug, and in order to do so increases the dose. All pleasure and security gained from the drug soon vanish and the process of deterioration sets in. It would appear to me more logical and kinder to treat this addiction with controlled doses of the drug. This would be arranged so that the minimum dose necessary to produce that indescribable sense of well-being for which the addict craves is given as required. Short periods of abstinence would be necessary when the minimum dose no longer produced the desired effect. These periods need be very short, as tolerance is lost rapidly. Hyoscine or a barbiturate could be given at these times.

The dreadful agony produced by the conventional form of treatment is indescribable and does not appear to justify the result. In your annotation (Dec. 13, 1947, p. 965) it is stated that "... treatment of this group is unnecessary, and possibly dangerous in that it may lead to true and progressive addiction." I would suggest that the "arrested development stage" of morphine addiction could be produced in most if not all cases, provided therapy is directed towards controlling and not curing this incurable condition.

The same principle might be applied to other forms of drug addiction.—I am, etc.,

London, W.9

F. R. ELLIS.

The Extent of Neurosis

SIR,—According to different observers it appears that between 10% and 50% of all who consult a doctor are sufferers principally from a neurosis. To these estimates must be added the many patients who do not go near a doctor for their neurotic troubles—either through ignorance, or through fear (sometimes justified) that these may not be objectively and sympathetically understood and dealt with. Taking this into consideration, even the most conservative estimate of the extent of neurosis must represent a degree of suffering and loss of efficiency, both national and in some cases individual, comparable in magnitude to that produced by the main physical diseases—tuberculosis, heart disease, rheumatism, cancer, etc. Despite this, however there is no provision made for training in the understanding and therapy of personality problems and the neuroses on any thing approaching an adequate scale.

In the training of the medical student there is little advance from the old days when the sole experience of functional disorders—apart from passing references to them in somewhat derivative terms: such as "purely neurotic" or "merely functional"—was confined to a few demonstrations of the more grotesque and advanced specimens from a mental hospital. In the training of the post graduate the situation is comparable: 50% of the theoretical instruction (and a large proportion of the practical) is given over entirely to the study of anatomy, physiology, and neurology. Of the remainder the bulk is occupied with the psychoses, physical methods of therapy, mental deficiency, legal aspects of insanity administration, etc., with a passing reference to Freud, Adler, Jung and others. On the clinical side the whole emphasis is on the mental

hospital—and increasingly so, it appears—where are assembled patients the majority of whom are psychotic or who have at least "broken down." These present, on the whole, problems very different from those of the ambulant cases, who have not "broken down" and who comprise the great majority of sufferers from the functional disorders.

The problem is a much wider one than the purely medical. A comparable situation exists in the sphere of academic psychology in this country. Here the main emphasis, theoretically and practically, is on such subjects as perception, reaction times, statistics, philosophy, and elementary physiology, to the almost total exclusion of clinical study and investigation into problems of motivation and personality.

Important as is the work of bodies such as the Tavistock Clinic, the Institute of Psycho-analysis, and of numerous gifted and conscientious individuals besides, they are left almost entirely to their own initiative and (necessarily limited) resources. It would be pertinent to ask what steps are envisaged by the authorities—Governmental, medical, and academic—responsible for the introduction and running of what purports to be a comprehensive health service, to cope with this vast problem, which amounts practically to a national emergency (if the available figures mean anything at all). What is being done to train the many psychologists—medical and non-medical—needed to cope adequately with these millions of sufferers from functional personality and behaviour disorders and to carry out research into their deeper causation?—I am, etc.,

London, N.6.

A. W. F. ERSKINE.

Synthetic Vitamin A

SIR,—I have read with interest the annotation on synthetic vitamin A (Dec. 27, 1947, p. 1040). This topic was also the subject of a recent leading article in the *Lancet*¹ and I have already written to the editor of the latter journal to make certain observations.

Regarding your annotation, I should like to indicate some inaccuracies concerning the work of van Dorp and Arens.² The C_{18} ketone, derived from β -ionone, was condensed with ethoxyethynylmagnesium bromide (and not the ethoxyethylene derivative) to give a disubstituted acetylene (which is not a C_{22} ketone). The product was then converted to vitamin-A aldehyde by the method summarized in your publication. As stated in your article, vitamin-A acid has been obtained by Arens and van Dorp,³ but it is also of interest to note that very similar syntheses were being studied simultaneously by both Heilbron⁴ in this country and Karrer⁵ in Switzerland, with their respective schools. The starting material, β -ionone, is of course only conveniently prepared from citral. Finally, I should like to draw your attention to the synthesis by Isler *et al.*⁶ of pure crystalline vitamin A by a method similar to that proposed earlier by Heilbron and his collaborators.⁷—I am, etc.,

London, S.W.7.

British Transport Medical Services

SIR,—Your leading article (Jan. 10, p. 54) prompts me to ask whether it would be possible for the Medical Department of the London Passenger Transport Board to arrange for the extraction of the dirt on the platforms and in the passages of their underground stations. Twice a day much of this dreadful mixture is swept up into the air after being watered, generally from a can without a rose so as to save time and lessen the effort. This method results in wetting the broom rather than the dirt. Were extraction done early in the morning and perhaps again before the evening rush the dangers of infection would be greatly diminished. Electricity is available at all necessary points and watering would not be required. Some twelve years ago I suggested this course to the Public Relations Officer, but nothing came of it. I am told that the coaches are just-extracted. Perhaps they are also aerosolled.

When the "Tuppenny Tube" was first opened there was no forced ventilation: the air was dry and irritating and had an

earthy smell. Max Rittenberg obtained permission to measure the humidity, confirmed the dryness, and suggested spraying the air with water. No notice was taken until each of us bought a share, attended the general meeting, and spoke of the matter. The provision of forced ventilation by conduits in the spiral staircases was the direct result of our trouble. The suggested spraying by means of the company's tunnel whitewashing-machine could clearly be adapted to aerosol disinfection if more simple means for this would not suffice.—I am, etc.,

London, W.1.

G. H. COLT.

POINTS FROM LETTERS

Censorship

Dr. G. C. PETHER (Hadley Wood, Herts) writes: I consider it essential that freedom of expression and publication should be accorded to those employed in a State medical service. Many of us are acquainted with attempts made for political reasons to silence doctors employed in municipal services, while those employed with the Armed Forces are controlled by certain regulations. . . . It is a small point among many more vital, but I should insist, if I entered a State service, that I could say what I liked regardless of persons or politics. Did not one of the fathers of democracy say that he entirely disagreed with a man's opinions but he would defend to the death his right to express them? Presumably we are still democrats?

Negative Health

Dr. G. L. DAVIES (Hove, Sussex) writes: . . . A good many years of practice among so-called working-class patients has revealed to me that one of the chief pastimes of the masses, apart from dominoes, darts, and drinking beer, is discussion—and that usually about health. But let us not be mistaken in thinking that this is intelligent talk on how to keep well. It is, in actual fact, luxurious wallowing in details of ill-health. Very casual observation over many years has shown me that my waiting-room is usually most crowded on a Monday or on a day following some public holiday. The inference is obvious: fire-side chats have been in progress, and the ghastly pallor (often largely imaginary) of Cousin Janc or the horrifying cough of Uncle John have been on the agenda, and the sufferers by unanimous vote have been recommended to see their respective doctors. This may be a wholesome piece of advice, but so frequently such talk about disease is merely the one and only conversation piece of a population educated at enormous expense by the State. State education, however, has had one important effect. It has produced a nation of newspaper readers and readers of much literary garbage of different kinds. Herein lies the clue to the disease-consciousness of the masses. The lower the standard, as a rule, of the paper the more is it filled with all kinds of specious advertisements related to disease. This fact is of course well known, but nothing is ever done to check this pandering to the ignorance and morbid instincts of the masses. One may have one's own opinion about the true purpose of the Commission now sitting on the Press, but here is one great evil to which it should give its undivided attention. . . .

Appendicitis Symptoms due to a Worm

Dr. A. S. GARRETT (Enugu, Nigeria) writes: In Nigeria appendicitis in any form is extremely rare. I therefore hesitated to diagnose it when I had a patient with a chronic pain in the right iliac fossa and a tender spot over McBurney's point. She had no other signs to suggest ovarian or other trouble. I operated, and found everything perfectly normal except for a calcified worm imbedded in the parietal peritoneum. There was no inflammation, but I can only assume that the worm was the cause of the symptoms.

Unclean Hairdressers

Mr. M. E. SPENCER HARRISON (Market Rasen, Lincs) writes: "Aurelia's" letter (Dec. 13, 1947, p. 978) concerning the condition of hairdressers' shops describes the other side of a situation which is assuming significant proportions. Otitis externa was a disease affecting chiefly the male, but of recent years one has noticed a preponderance of female cases in the out-patient departments. With the ears continually covered by the hair, it is not surprising that, once established, an infection which arises primarily in the scalp will be resistant to treatment.

Fluids and Sulphonamides

Dr. BERNARD ROWLANDS (Tunbridge Wells) writes: While the relative toxicity of sulphamerazine, sulphathiazole, and other sulphonamides is being investigated and discussed, I would like to emphasize the fact that there is inadequate supervision of the amounts of fluid taken by patients who are being treated by these drugs. No doubt this supervision is very difficult in large hospitals. I speak from personal experience.

Obituary

A. C. DOUGLAS FIRTH, M.D., F.R.C.P.

Dr. Douglas Firth died suddenly at Cambridge at the age of 67 on Jan. 9. His friends knew that a few years ago he had had a warning of the disease which finally struck him down, but he had been so well in the interval, and so cheerful, that they were apt to forget that he was not in robust health.

Arthur Charles Douglas Firth, son of Charles Frederick Firth, of The Briary, Harrogate, was born on Feb. 10, 1880, and was educated at Harrow (Church Hill, Mr. J. C. Moss's House) and Trinity College, Cambridge, where he graduated B.A. in 1901, proceeding M.A. in 1905. As an undergraduate he was coxswain of the first Trinity boat. On coming down from Cambridge he went to St. Thomas's Hospital, where he took his M.B. in 1911. He was admitted M.R.C.P. in 1912, and went on to take the Cambridge M.D. in 1914. He soon became known as one of the young men well qualified to take up a post in a teaching hospital, and he was appointed assistant physician to the Royal Free Hospital, the Victoria Hospital for Children, the City of London Hospital for Diseases of the Chest, and the Royal National Orthopaedic Hospital. In 1919 he became assistant physician at King's College Hospital, retiring then from the staff of the Royal Free Hospital, and in the following year he was elected a fellow of the Royal College of Physicians. It was at King's College Hospital that most of his teaching work was done, and he became senior physician on the retirement of Sir Charlton Briscoe.

Firth loved teaching, and he particularly liked to teach the young student the first steps in clinical medicine. He brought to this important task a simplicity and an earnestness that were most impressive. He was also an examiner in, among other places, London, Cambridge, and Glasgow, and he treated the candidates with that kindness which was characteristic of him. Apart from his teaching work he carried on a large practice and was consulting physician to a number of small hospitals in Surrey and Kent, where his opinion was greatly valued by many general practitioners.

On the outbreak of war he played a great part in the transfer of King's College Hospital to the Sector Hospitals and was in charge of the teaching of students at Leatherhead Emergency Hospital. At this time he gave up private practice and devoted himself to hospital work. He took great pleasure in this, as he had charge of the students in their earliest days of clinical work, and he took care not only of their teaching but also of their social life. At the same time he became active in the affairs of the Royal College of Physicians and was elected a member of council in 1939, a censor of the College from 1940 to 1942, and in 1945 became senior censor. During this period, as it was difficult to arrange the examination for the M.R.C.P. in London, he made the necessary arrangements for the examination to be held in the Emergency Sector Hospitals.

In 1940 he was due to retire from the staff at King's, but owing to the war he remained on as senior physician, and when the war was over he was appointed to Cambridge University, taking charge of the arrangements for the postgraduate work of returning Service officers. This appointment necessitated his living in Cambridge and retirement from King's, and it also brought him the added pleasure, and honour, of being made a Fellow of Trinity Hall, Cambridge. Between the wars, while in active practice, his home in Manchester Square was the scene of many social functions where Firth and his wife delighted in entertaining their friends. He married in 1914 Violet Dorothea, daughter of Lieut.-Col. H. N. Reeves, of the Bombay Political Service, and had a son and three daughters. Firth's chief recreation, which was shared by his family, was walking, and their holidays and leisure were chiefly spent in the Lake District, which he loved and knew intimately. His death will be mourned by his old students throughout the world, and our sympathies go out to his widow and children in their sudden bereavement.

Prof. J. W. McNee writes: Douglas Firth had not many close friends and I was fortunate to be one of them. He had

a deep reserve through which few were allowed to penetrate, and many interesting facts of his good life are unlikely to be well known. His reserve was not easily detected, for he enjoyed good company and good conversation, and his quick eager voice and ready smile enlivened many a social evening or an otherwise dull examiners' meeting. He completed his clinical studies at St. Thomas's Hospital and, after qualifying, became house accoucheur to Mr. Tate. Then followed appointments as H.S. and H.P. at West London Hospital, to be succeeded by a most successful time as R.M.O. at the Victoria Hospital for Children, Tite Street. Firth loved children, and his success at this hospital was so great that he was made an honorary consulting physician, a post which he retained with pride for many years.

His marriage in 1914 was a very happy one, and his professional career seemed assured. When war broke out he began to assemble a Red Cross Ambulance Unit intended to serve with the French Army, but almost immediately serious illness overtook him which lasted a long time and seriously complicated his career. In 1915 he had recovered sufficiently to enter the R.A.M.C. but was always rejected for service overseas. In 1916 illness returned and lasted almost continuously until 1919. In October, 1919, he was appointed assistant physician to King's College Hospital, and from then onwards his health steadily improved and his career was never again disturbed. A wise decision, however, took him into the City as consultant physician to three large insurance companies, which saved him much of the harassing work and travel of an ordinary consultant. I first met Firth as a co-examiner in the Final M.B. at Cambridge, and subsequently we examined together on many occasions both there and in Glasgow. Firth liked examining because he was always so young in spirit himself and loved young people—some of his happiest hours in Scotland were probably spent in animated discussion with my young assistants.

Firth had an unusual hobby, recorded in *Who's Who* as "Postal History," which puzzled many people. He was an expert philatelist, but specialized in an interesting branch only known to a few. He collected ships' letters—that is to say, letters sent home in the early days of our colonial history through the captains of small brigs and sailing ships, to be posted and post-marked at small and now-forgotten ports such as Poole, Rye, Bantry, Galway, and many others. He found, to my astonishment, another collector of ships' letters in Glasgow with whom he would occasionally exchange notes and duplicates. Firth did not write much on modern medicine but was greatly interested in general and medical history. One of his most delightful essays was on the first case of disseminated sclerosis described in English by the patient himself—"The Case of Augustus d'Este," published in the *Proceedings of the Royal Society of Medicine* in 1941.

On his retirement from King's College Hospital after the second world war Firth was soon given a post at Cambridge which ensured his contact with young doctors and which suited him perfectly. To this was added the joy of his election as a Fellow of Trinity Hall, and his life was full until his first coronary attack a year or two ago gave him a warning; like the first, the second attack came suddenly, and proved fatal. Douglas Firth was a perfect example of the courteous and cultivated general physician, and his death is a great loss to all the young members of the profession whom he helped so much as well as to the friends of his own generation.

E. W. HEDLEY, M.B.E., M.D.

Dr. E. W. Hedley, who died at his home at Thursley, near Hindhead, on Jan. 3 at the age of 74, was consulting anaesthetist to St. Thomas's Hospital. He had been living in retirement for the last ten years.

Edward Williams Hedley was the eldest son of a large family. He was born in Middlesbrough, and at Uppingham he won the scholarship which took him to King's College, Cambridge. There he took a first in the first part of the natural science tripos, and he graduated M.B., B.Ch. as a student of St. Thomas's in 1900. He proceeded M.D. five years later. Meanwhile he had acted as a house-physician and later as obstetric house-physician at St. Thomas's, and he was also a clinical assistant at the West London and the Brompton

Hospitals. He was in general practice for a while, but when a vacancy occurred at St. Thomas's he was elected to the staff as an anaesthetist. When the hospital became the 5th London General Hospital during the 1914-18 war Hedley was commissioned in the R.A.M.C. with the rank of captain and did a great deal of work there and at several officers' hospitals in London. He was awarded the M.B.E. in recognition of his services in this connexion. On reaching the age limit he was made a consulting anaesthetist and elected a governor of the hospital.

He leaves a widow, two sons, and two daughters, and he will be greatly missed by many former colleagues and students who were grateful to him for much sound teaching.

Mr. JOHN JAMES ROBB, the well-known Dundee surgeon, died suddenly at his home at the age of 50 on Jan. 2. Mr. Robb was a son of the Scottish manse and was born in Kemnay, Aberdeenshire. Before starting medicine he held a commission in the Royal Horse Artillery, and was awarded the Military Cross while serving in France during the 1914-18 war. In the early years of his medical studies at Edinburgh he took a high place in the examinations in physiology and pathology and was appointed demonstrator in these subjects. After graduating M.B., Ch.B. in 1923 he filled various resident posts in Edinburgh Royal Infirmary, and it was then that he found his interests lay in surgery. After leaving the Infirmary his first post was with the Ministry of Pensions under Mr. Mercer in Edinburgh and later he was transferred to Bath. He took the F.R.C.S.Ed. in 1926, and thereafter, on obtaining a surgical appointment at the Bristol General Hospital, he was made assistant to the professor of surgery in the University of Bristol.

A colleague writes: For the next five years Mr. Robb occupied the important position of consulting surgeon to the County of Zetland and surgeon to the Gilbert Bain Hospital, Lerwick. The appointment of honorary assistant surgeon to Dundee Royal Infirmary came in 1933, followed by promotion to honorary surgeon in 1940. At the same time he was appointed lecturer in clinical surgery in the University of St. Andrews. He was also surgeon to Ashludie Sanatorium, King's Cross Infectious Diseases Hospital, the Royal Victoria Hospital, and Meigle Hospital. Mr. Robb contributed to the medical journals on various subjects, but his main interest was in abdominal surgery. He spent many of his holidays visiting hospitals abroad. Mr. Robb quickly settled down in Dundee to his work as a hospital surgeon and teacher of students—work which was arduous but always congenial and always conscientiously done. He was a man of unruffled temperament and of great kindness and personal charm. He never seemed hurried or harassed by pressure of work, and although his working day was often a long one, he answered every call with cheerfulness. He will be much missed by the many who sought his advice and help. Deep sympathy is extended to Mrs. Robb and his young son and daughter in their bereavement.

Dr. ALEXANDER TAYLOR WOODWARD died at the early age of 52 after a long period of ill health—actually over two years. He was educated at Taunton School, Somerset, and Edinburgh University, where he graduated M.B., Ch.B. in 1917. Before graduating he served as a surgeon-probationer and afterwards as a temporary surgeon, R.N., in the 1914-18 war. He was later a house-surgeon at the Royal Infirmary, Edinburgh, and at the Sunderland Royal Infirmary. In 1920 he settled in general practice in Sunderland, his native town, and quickly became a popular and busy practitioner. He was an active member of the British Medical Association, serving on the National Formulary Subcommittee from 1928 to 1933; he was chairman of the Sunderland Division in 1937-8. He was an assistant physician at the Monkwearmouth and Southwick Hospital and an honorary life member of St. John Ambulance Association, for which he was an examiner. His loss will be keenly felt by his patients, colleagues, and many friends.

Dr. THOMAS EDWARDS READE, of Banbridge, Co. Down, died suddenly, following a heart attack, on Jan. 5 at the early age of 40. The elder son of the late Adam Reade, he was educated at Queen's University, Belfast, where he graduated M.A., B.Ch., in 1911. After qualifying he held resident posts as a house-surgeon and house-surgeon at the Royal Victoria Hospital, Belfast. He settled in Banbridge about eleven years ago, and was in the practice of Dr. Robert Martin and the post of Medical Officer, Banbridge, and the Post

Office; he was also certifying factory surgeon for the district. During the war he rendered valuable service as an officer in the Home Guard and for a time he attended the troops stationed at Gilford. He was an enthusiastic member of the Banbridge and District Medical Club, of which he was secretary and treasurer. His high degree of professional skill and his sound clinical judgment were recognized by both patients and colleagues, and his untimely death is mourned by a host of friends. He married the daughter of Dr. William Boyd and Mrs. Boyd, of Banbridge, who survives him.—R. S. A.

Universities and Colleges

UNIVERSITY OF OXFORD

In a Congregation held on Dec. 13, 1947, the following degrees were conferred:

B.M.—P. J. R. Nichols, E. M. Vaughan Williams, P. B. Croft, W. H. I. Fairbank, J. H. Lloyd Jones, B. R. Hunt, P. S. Moore, Mrs. Anne G. Marie Sadka.

1 In absence.

UNIVERSITY OF LONDON

The following candidates at the London School of Hygiene and Tropical Medicine have been approved at the examination indicated:

ACADEMIC POSTGRADUATE CERTIFICATE IN PUBLIC HEALTH.—M. H. Abdulcader, A. A. Cameron, P. J. Cowin, C. W. Davies, G. J. Li. Davies, M. A. Dowling, D. F. Eastcott, Patricia M. Elliott, D. G. Evans, J. Glass, Margot Graham, V. T. H. Gunaratne, Helen E. E. Gunn, M. N. Gupta, Kathleen Harding, E. A. Hargreaves, J. A. Harrington, J. P. Harrison, S. I. Heinsheir, N. S. Hepburn, G. R. Holtby, B. E. C. Hopwood, J. B. Kershaw, L. Kulczycki, R. G. Larkin, A. H. MacGeachy, I. W. MacKiehan, Oliver R. Major, Phyllis Morley, Margaret E. Munro, G. D. K. Needham, A. J. Patterson, P. A. B. Ral, A. T. Roden, F. Schulz, E. S. O. Smith, C. N. D. Taylor, S. W. W. Terry, W. Thorburn, P. Tomlinson, S. J. Walsh, Edith H. Williams, N. Williams, J. Wilson, W. A. Wilson, G. M. Wright.

ROYAL COLLEGE OF SURGEONS OF ENGLAND

At a quarterly meeting of the Council of the College held Jan. 8, with Sir Alfred Webb-Johnson, Bt., President, in the chair, the following resolution of condolence was passed on the death of Mr. G. F. Stebbing, a Member of the Council: "The President of the Council of the Royal College of Surgeons of England hereby expresses their deep regret at the death of Mr. George French Stebbing and their sincere sympathy with Mrs. Stebbing and her family in their bereavement. The medical profession has suffered the loss of a surgeon and radiotherapist of ability and vision, who will be remembered for his quiet and unswerving determination to achieve what he knew to be right. The Council mourn the passing of a wise counsellor and beloved colleague."

Prof. Geoffrey Hadfield, M.D., was appointed Sir William Collins Professor of Human and Comparative Pathology of the College.

The following hospital was recognized in respect of the residential surgical posts required of candidates for the Final Fellowship examination: Tindal Hospital, Aylesbury (resident surgical officer and house-surgeon).

Diplomas of Fellowship were granted to M. S. Brett and P. A. Ring.

A Diploma of Membership was granted to J. Davenport.

Diplomas in Tropical Medicine and Hygiene; Psychological Medicine; Laryngology and Otolaryngology; Anaesthetics; and Industrial Health were granted, jointly with the Royal College of Physicians of London, to the following successful candidates:

DIPLOMA IN TROPICAL MEDICINE AND HYGIENE.—B. L. P. Brosseau, J. D. Cruickshank, A. J. Fulthorpe, D. B. Jelliffe, L. F. Koyl, S. Miles, A. M. Peck, P. D. Stewart.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.—E. S. Foote, W. Forster, C. E. L. Haffner, H. E. W. Hardenberg, N. C. Horne, S. Karagulla, M. Klass, H. S. Klein, A. Lask, N. Morrissey, D. F. O'Neill, Nydia E. Pantom, M. Silverman, Margaret S. S. Small, Jeannie E. Stirling, C. Tellow, J. I. Timothy, V. J. K. Wright.

DIPLOMA IN LARYNGOLOGY AND OTOLARYNGOLOGY.—H. Anderson, L. V. Arnold, J. C. Ballantyne, B. Bellon, G. R. Evans, J. Fine, H. S. Gild, E. W. Jarrah, R. H. S. Lee, J. L. Morris, K. O'Brien, M. A. O'Brien, H. B. Pickard, Q. R. Schindler, A. K. Sear, B. K. Sengupta, R. Smith, R. W. Tipler.

DIPLOMA IN ANAESTHETICS.—J. J. L. Ablett, Aileen K. Adams, J. T. Anderson, G. E. Badman, I. N. Bahl, H. C. J. Ball, A. K. Bannister, V. B. Bhargava, Jocelyn P. Bodington, J. A. Bowen-Jones, H. C. Burbidge, G. W. Campbell, D. M. Carrere, J. H. Challenger, H. J. E. Christie, S. Citron, R. F. Connell, H. S. A. Corfield, J. L. S. Cresswell, D. Dangerfield, A. Danin, D. H. Davies, Doreen Davies, G. G. Donaldson, C. H. Dunn, W. O. M. Ede, E. M. Edwards, J. L. C. Fernandez, R. A. Fisher, F. W. A. Fosbery, C. M. Friedland, J. P. Gallie, R. E. Gibson, L. A. Gifford, Muriel M. Gloster, R. N. Grabowsky-Atherstone, Margaret A. Griffiths, J. Hamilton, Phoebe N. Harvey, D. R. Hughes, A. M. Hutton, J. N. T. Hutton, D. H. Irish, L. H. James, H. Jefferson, J. Johnston, D. F. McAlpine, G. McLoughlin, M. C. Macqueen, H. B. Maliphant, J. P. Murphy, A. O'Connor, Barbara D. Owens, J. G. Peacock, G. F. Purves, L. Rendell-Baker, J. R. Rock, E. H. Seward, D. W. Shannon, J. C. Skelley, A. C. Smith, G. H. Stuart, V. V. Tarvadi, L. L. Theron, Betty Thomas, J. M. van de Walle, F. van Nieuwen, N. S. Wallis, H. Waters, D. S. Wilson, J. R. J. Winter, J. Woodley, A. P. Wright, G. V. S. Wright.

DIPLOMA IN INDUSTRIAL HEALTH.—G. Buchanan, H. F. Chard, F. H. Kirk, P. Pringle, M. W. Robinson, R. S. F. Schilling, C. L. Sutherland, A. Li. Thompson, D. R. Thompson, H. Wyers.

No. 1

EPIDEMIOLOGICAL NOTES

INFECTIOUS DISEASES AND VITAL STATISTICS

We print below a summary of Infectious Diseases and Vital Statistics in the British Isles during the week ended Jan. 3.

Figures of Principal Notifiable Diseases for the week and those for the corresponding week last year, for: (a) England and Wales (London included). (b) London (administrative county). (c) Scotland. (d) Eire. (e) Northern Ireland.

Figures of Births and Deaths, and of Deaths recorded under each infectious disease, are for: (a) The 126 great towns in England and Wales (including London). (b) London (administrative county). (c) The 16 principal towns in Scotland. (d) The 13 principal towns in Eire. (e) The 10 principal towns in Northern Ireland.

A dash — denotes no cases; a blank space denotes disease not notifiable or no return available.

Disease	1948					1947 (Corresponding Week)

Rate per 1,000 total births (including stillborn)	—	—	26	—	—	—	—	29	—	—

* Measles and whooping-cough are not notifiable in Scotland, and the returns are therefore an approximation only.

† Includes primary form for England and Wales, London (administrative county), and Northern Ireland.

‡ Includes puerperal fever for England and Wales and Eire.

Poliomyelitis

Notifications of poliomyelitis in England and Wales in the week ending Jan. 10 were 52 (59) and of polio-encephalitis 6 (4). Figures for the previous week are shown in parentheses. The hope lately expressed in these notes that notifications would fall to their normal winter level by the middle or end of February now seems unlikely to be fulfilled.

Discussion of Table

In England and Wales an increased incidence was recorded for all notifiable diseases. The increases included measles 1,907, whooping-cough 750, acute pneumonia 408, scarlet fever 317, diphtheria 68, dysentery 33, paratyphoid fever 17.

A large increase in the notifications of measles was recorded throughout the country and the total was the largest since the beginning of August. The largest rises during the week were Lancashire 185, Durham 152, London 136, Monmouthshire 104, Sussex 98, Lincolnshire 93, and Nottinghamshire 90.

The largest increases in the notifications of whooping-cough were London 68, Kent 56, and Yorkshire West Riding 46. An increase in the incidence of scarlet fever was also recorded in all regions; the largest rise was Staffordshire 41. The notifications of acute pneumonia were the largest since February, and the largest increase was London 61. The chief features of the returns for diphtheria were increases in Essex 14, Durham 11, and Warwickshire 11.

No fresh outbreaks of dysentery of any size were reported; the largest returns were Lancashire 21, London 11, and Surrey 9. A further 21 cases of paratyphoid were notified from the outbreak in Suffolk; 14 of these were reported from Ipswich C.B.

The largest returns of poliomyelitis during the week were those of London 7 (Shoreditch 3), Middlesex 6, Lancashire 5, Surrey 5.

In Scotland infectious diseases were less prevalent than in the preceding week. There were decreases in the notifications of measles 115, acute primary pneumonia 88, and diphtheria 34, while the largest rise was in the notifications of cerebrospinal fever 10. Of the 5 cases of acute poliomyelitis 3 were notified in the city of Glasgow.

In Eire rises were recorded in the incidence of measles 81, whooping-cough 38, acute primary pneumonia 30, scarlet fever 24, and diarrhoea and enteritis 23. The rise in the incidence of scarlet fever and measles was fairly general throughout the country, while the increase in cases of whooping-cough was contributed by Dublin C.B. and Waterford C.B.

In Northern Ireland a rise was reported in the incidence of measles 16 and scarlet fever 13. The former was due to an outbreak in Antrim county and the latter to the experience of Belfast C.B.

Quarterly Returns for Eire

The birth rate during the September quarter of 1947 was 23.4 per 1,000, the highest rate in a third quarter since 1942. The infant mortality of 47 per 1,000 births was 7 below the rate for the September quarter of 1946 and 26 below the rate for the third quarter of 1943. Maternal mortality was 1.8 per 1,000 registered births and was 0.2 above the rate for the corresponding quarter of 1946. The general death rate was 11.2, being 0.3 below the rate for the third quarter of 1946. Deaths from diarrhoea and enteritis among infants under 2 years numbered 156; this total was 168 below the average of the third quarters of the five preceding years. Only 10 deaths were attributed to diphtheria—a figure which was 39 below the five years' average. The 43 deaths from measles were 34 above the average of the last five third quarters. Deaths from pulmonary tuberculosis were 636 and from other forms of tuberculosis 219; these were 75 and 35, respectively, above the number recorded in the third quarter of 1946.

Infectious Diseases in 1947 in England and Wales

The number of notifications of diphtheria in 1947 was the lowest ever recorded. There has been a steady decline in the incidence of diphtheria since 1942, and it is now about one-sixth of the immediate pre-war level. The lowest number of weekly notifications in 1947 was 138, compared with 815 and 788 in 1938 and 1937, and the largest weekly total in 1947 was 256 as against 1,889 in 1938 and 1,823 in 1937. The decline in the notifications of cerebrospinal fever since the outbreak in 1940, when 12,791 cases were notified during the year, has been interrupted and the notifications in 1947 were slightly above the totals for the three preceding years.

The large decrease in the incidence of dysentery recorded in 1946 has been repeated and the disease has now reverted to the pre-war level. Notifications of typhoid and paratyphoid

were considerably fewer than in 1946 but were above the level of the three years preceding 1946. In the outbreak of acute poliomyelitis, perhaps the chief feature of 1947, the notifications exceeded 600 per week for the four weeks from the 33rd-36th week, compared with 10 to 30 cases in the preceding four years. A comparison of the totals recorded during the last five years is:

	Number of Notifications				
	1943	1944	1945	1946	1947
Scarlet fever	116,217	93,801	74,392	57,614	60,524
Whooping-cough .. .	95,857	93,107	62,022	92,028	94,241
Diphtheria	35,944	29,446	25,059	18,156	10,528
Measles	374,198	117,437	443,002	154,826	399,461
Acute pneumonia .. .	52,225	38,175	34,059	36,106	34,348
Cerebrospinal fever ..	3,380	2,883	2,691	2,627	3,147
Dysentery	7,772	10,150	16,533	8,441	4,179
Enteric (paratyphoid and typhoid) fevers ..	707	536	679	1,367	880
Acute poliomyelitis ..	414	510	799	703	8,592
Influenza. Deaths in the great towns ..	6,280	1,744	1,307	2,629	1,774

Week Ending January 10

The notifications of infectious diseases in England and Wales during the week included: scarlet fever 1,525, whooping-cough 2,057, diphtheria 216, measles 3,746, acute pneumonia 975, cerebrospinal fever 60, acute poliomyelitis 52, dysentery 114, paratyphoid 8, and typhoid 3.

The Services

The War Office has announced that Major-General Neil Cantlie, C.B., M.C., late R.A.M.C., will succeed Lieutenant-General Sir Alexander Hood, G.B.E., K.C.B., as Director-General, Army Medical Services, on April 1.

Captain S. S. Pavillard, M.B., Ch.B., Straits Settlement Volunteer Force, has been appointed M.B.E. (Military Division) in recognition of gallant and distinguished services while a prisoner-of-war in Japanese hands (prior to September, 1945).

The King of the Hellenes has conferred the following decorations in recognition of distinguished services in the cause of the Allies:

Commander of the Royal Order of King George I with Swords.—Brigadier (Temporary) F. R. Sandford, C.B.E., M.C., T.D., late R.A.M.C.

Knight of the Royal Order of King George I with Swords.—Major (Temporary) W. F. Felton, R.A.M.C.

The President of the U.S.A. has conferred the following decorations in recognition of distinguished services in the cause of the Allies:

Legion of Merit, Degree of Officer—Lieutenant-Colonel W. B. F. Brennan, R.A.M.C.

Bronze Star Medal.—Lieutenant-colonel (Temporary) J. M. Barnes and Major H. G. Skinner, R.A.M.C.

The Queen of the Netherlands has conferred the following decorations in recognition of distinguished services in the cause of the Allies:

Commander of the Order of Orange Nassau with Swords.—Colonel T. F. Kennedy, O.B.E., late R.A.M.C., and Lieutenant-Colonel J. P. Douglas, O.B.E., R.A.M.C.

Officer of the Order of Orange Nassau with Swords.—Colonel (Acting) A. F. Kennedy and Lieutenant-Colonel (Acting) M. S. Harvey, R.A.M.C.

Medical News

Sickness Benefit Regulations

The National Insurance Advisory Committee will report on the proposed amendments to Sickness Benefit Regulations (H.M.S.O., price 10s. 6d.) made under the National Insurance Act, 1946. Written representations to the preliminary draft of the regulations will be considered by the Committee and should be sent before Feb. 6 to the Secretary, National Insurance Advisory Committee, 6, Curzon Street, London, W.1.

Medical Conferences Proposed

Dr. F. C. M. B. Jones, M.D., has proposed to ex-servicemen in London a conference on the subject of the supplementary ration book. The conference will be held on Feb. 10, 1948, at 10.15 a.m. at the Royal College of Physicians, 11, St Andrews Place, Regent's Park, London, N.W.1. The conference will be held for the purpose of discussing the ration book and the medical profession's views on it.

Committee on Health Centres

When the Central Health Services Council has been formed the Minister of Health proposes to set up a committee in collaboration with it to gather information and proffer expert guidance on the best kinds of health centres to develop.

Royal Sanitary Institute Prizes

The Royal Sanitary Institute offers the John Edward Worth Prize of £40 for an essay on "Practical Improvements of Appliances or Inventions in or about Dwelling-houses," and the John S. Owens Prize of £15 for an essay on "Atmospheric Pollution." A copy of the general conditions may be obtained from the secretary of the Institute, 90, Buckingham Palace Road, London, S.W.1. Entries must be submitted by Dec. 31.

Pharmacists' College

The Pharmaceutical Society of Great Britain has decided that the steady rise in costs and salaries makes it impossible to continue to maintain its College as it has done since it was founded in 1842. After consultation with the University of London it has therefore proposed that the College should become an independent corporate body governed by a Council including representatives of the Society, the University, the academic staff, and the pharmaceutical profession and industry. The College would remain a "school" of the University. The Society and the University are now discussing a proposal that the latter should take over the building in Brunswick Square intended to house the College, on which the Society has already spent £200,000 and for which as much again would be needed to complete it at present-day prices.

Peter Edwards Ward

An extension of the Cheshire Joint Sanatorium at Loggerheads, near Market Drayton, was opened on Dec. 5. It has been named the Peter Edwards Ward in recognition of the long and faithful services rendered by Dr. Peter W. Edwards.

Liverpool Heart Hospital

In order to obtain more space, particularly for treatment by graduated exercise, the Liverpool Heart Hospital has acquired Caldys Manor. The site covers 13 acres of land in sheltered countryside.

Foundling Estate

The Dominion Students' Hall Trust, in order to provide scope for its increasing activities and with a view to furthering ancillary objectives of a charitable or educational nature centred in Bloomsbury, has acquired the Foundling Estate, which surrounds its headquarters at London House, Guilford Street. The Estate was bought about 1740 by Captain Coram, the renowned sailor, to endow the old Foundling Hospital for children. The hospital itself was moved to Berkhamsted in 1926.

British Association

Prof. H. Hartridge, F.R.S., has been appointed president of the physiology section of the British Association.

To Lecture in Scandinavia

Prof. Macintosh, Nuffield Professor of Anaesthetics in the University of Oxford, leaves Britain on Jan. 24 for a lecture tour on behalf of the British Council in Finland, Sweden, and Denmark.

Gift to Polish Clinic

The Polish Ambassador received a thoracoscope on Jan. 15 from the Cultural Subcommittee of the British-Polish Society. It is inscribed in English and Polish: "Presented by the British-Polish Society, London, to the University Tuberculosis Clinic, Wroclaw."

Wills

Sir Thomas John Carey Evans, of Crickieth, left £23,172. Dr. Reginald Cecil Bligh Wall, formerly archivist to the Society of Apothecaries, left £8,305.

COMING EVENTS

Services Hygiene Officers' Dinner

Brigadier A. E. Richmond will deliver his presidential address before the Navy, Army, and Air Force Hygiene Group of the Society of Medical Officers of Health at B.M.A. House, Tavistock Square, London, W.C., on Friday, Jan. 30, at 5 p.m. (not 5.30 p.m. as announced in this column last week). The reunion dinner of the group will be held at the time and place arranged.

Meeting for Prayer

A prayer meeting for medical men who are professing Christians will be held on Thursday, Jan. 29, at Livingstone House, Broadway, Westminster, London, from 3.45 to 4.45 p.m. It will be preceded by tea and light refreshments at 3.30 p.m.

Association of Industrial Medical Officers

A meeting of the Association of Industrial Medical Officers will be held at the London School of Hygiene and Tropical Medicine, Keppel Street, W.C., on Friday and Saturday, Jan. 30 and 31, 1948. On Jan. 30, at 5.15 p.m., Dr. C. M. Fletcher will speak on "Coal Miners' Pneumoconiosis and Recent Developments." A dinner at the Connaught Rooms (Great Queen Street, London, W.C.) will follow. On Jan. 31, at 10.30 a.m., Prof. E. J. King will discuss "Recent Developments in the Study and Treatment of Silicosis."

Association of Clinical Pathologists

The Association of Clinical Pathologists will celebrate its coming-of-age with a dinner at the Piccadilly Hotel, London, W., on Friday, Jan. 30, at 7.30 p.m. for 8 p.m.

Course on Medical Treatment

The University of Leeds Postgraduate Committee has arranged a clinical week-end course devoted to the subject of medical treatment, and open to general practitioners and others interested, to be held at the General Infirmary at Leeds on Feb. 21 and 22. The fee for the course is £1 ls. Further information and application forms may be obtained from the Senior Administrative Officer, School of Medicine, Leeds, 2.

SOCIETIES AND LECTURES

Monday

BRITISH INSTITUTE OF PHILOSOPHY.—At University Hall, 14, Gordon Square, London, W.C., Jan. 26, 5.15 p.m. "Existentialism." Prof H. J. Paton.

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY, 330-332, Gray's Inn Road, London, W.C.—Jan. 26, 2 p.m. "Headache." Mr. W. M. Mollison.

ROYAL SOCIETY OF ARTS, John Adam Street, Adelphi, London, W.C.—Jan. 26, 4.30 p.m. "The Common Cold." Cantor Lecture by Dr. C. H. Andrewes, F.R.S.

Tuesday

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—Jan. 27, 5 p.m. "The Scleroderma." Dr. Hugh Gordon.

UNIVERSITY COLLEGE LONDON: DEPARTMENT OF PHARMACOLOGY. Gower Street, W.C.—Jan. 27, 5.15 p.m. "Symptomatic Drugs. Sympathomimetics and Sympatholytics." Mr. F. Bergel.

Wednesday

EDINBURGH CLINICAL CLUB.—At Edinburgh Royal Infirmary, Jan. 28, 4 p.m. "Surgical Aspects of the Treatment of Peptic Ulcer." Prof. J. R. Learmonth.

INSTITUTE OF LARYNGOLOGY AND OTOTOLOGY, 330-332, Gray's Inn Road, London, W.C.—Jan. 28, 4.30 p.m. "The Larynx." "Organic Nervous Affections of the Larynx." "Laryngeal Paralysis. Treatment—Educational and Operative." Mr. V. E. Negus.

ROYAL SOCIETY OF ARTS, John Adam Street, Adelphi, London, W.C.—Jan. 28, 2.30 p.m. "Recent Progress in the Making of Precision Instruments." Mr. A. J. Philpot.

Thursday

INSTITUTE OF DERMATOLOGY, 5, Lisle Street, Leicester Square, London, W.C.—Jan. 29, 5 p.m. "Dermatoses due to Filtrable Virus." Dr. G. B. Mitchell-Heggs.

ROYAL PHOTOGRAPHIC SOCIETY OF GREAT BRITAIN (SCIENTIFIC AND TECHNICAL GROUP), 16, Prince's Gate, London, S.W.—Jan. 29, 7 p.m. "Photographic Visual Aids." D. A. Spencer, Ph.D., Hon. F.R.P.S.

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS.—At Royal Society of Medicine, 1, Wimpole Street, London, W., Jan. 29, 2.30 p.m. Joint meeting of the Physical Methods Group and the Biological Methods Group. Subject of meeting: "Methods of Penicillin Assay—Their Purpose, Scope and Validity."

ST. GEORGE'S HOSPITAL MEDICAL SCHOOL, Hyde Park Corner, S.W.—Jan. 29, 4.30 p.m. "Psychiatric Lecture-demonstration." Dr. D. Curran.

Friday

KENT AND CANTERBURY HOSPITAL.—Jan. 30, 5 p.m. Clinical meeting. Demonstration of Cases.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—At Pathology Department, School of Medicine, Leeds, Jan. 30, 8.30 p.m. Pathological meeting.

LONDON CHEST HOSPITAL, Victoria Park, E.—Jan. 30, 5 p.m. "Selection of Cases for Artificial Pneumothorax." Dr. E. H. Hudson.

ROYAL MEDICAL SOCIETY, 7, Melbourne Place, Edinburgh.—Jan. 30, 8 p.m. "The Rh Factor Assessment in Disease." Dissertation by Mr. J. S. Barrett.

UNIVERSITY COLLEGE LONDON: DEPARTMENT OF PHYSIOLOGY. Gower Street, W.C.—Jan. 30, 5 p.m. "The Living Fabric: Blood and Breath." Dr. E. A. Underwood.

APPOINTMENTS

Jung Bahadur Singh, O.B.E., L.R.C.P.&S.Ed., and Jacob Alexander Nicholson, M.B., Ch.B.Ed., have been appointed Unofficial Members of the Executive Council of the Colony of British Guiana.

GAWNE, STANLEY C., M.D., D.P.H., Deputy County Medical Officer for Lancashire.

HOLMES, J. MACD., M.D., M.R.C.P., Visiting Neurological Physician, Wrexham County (E.M.S.) and War Memorial Hospitals.

HOWIE, JAMES ERSKINE, M.D., D.P.M., Regional Psychiatrist, Liverpool Regional Hospital Board.

KING'S COLLEGE HOSPITAL MEDICAL SCHOOL.—*Directors of Clinical Studies (Part-time):* Medicine, Terence East, D.M., F.R.C.P.; Surgery, Sir Cecil P. G. Wakeley, F.R.C.S.; Obstetrics and Gynaecology, J. H. Peel, F.R.C.S., F.R.C.O.G.; Child Health, Wilfrid Sheldon, M.D., F.R.C.P. *Honorary Teaching Staff:* A. H. Galley, M.B., B.S., D.A., Assistant Anaesthetist, A. J. Heriot, M.S., F.R.C.S., Assistant Surgeon, R. S. Lewis, F.R.C.S., Assistant Surgeon for diseases of the Ear, Nose, and Throat, Samuel Oram, M.D., Assistant Physician, Dennis Hill, M.B., B.S., Physician in Psychological Medicine, S. G. Clayton, M.D., M.S., F.R.C.S., Assistant Obstetric and Gynaecological Surgeon, D. I. Williams, M.B., B.S., Assistant Physician for Diseases of the Skin. *Full-time Staff:* A. H. Baynes, M.B., B.Chir., Acting Assistant Chemical Pathologist and Demonstrator in Chemical Pathology, G. F. M. Hall, M.B., Ch.B., Demonstrator in Morbid Anatomy, A. C. Cunliffe, M.B., B.Chir., Assistant Bacteriologist and Lecturer in Bacteriology.

MIDDLESEX COUNTY COUNCIL.—At West Middlesex County Hospital: Dermatologist: F. J. V. Jenner, M.R.C.P.; Director of Department of Physical Medicine: D. M. L. Doran, B.M., B.Ch.

MILNE, JAMES, M.B., Ch.B., D.P.M., Deputy Medical Superintendent, Fife District Asylum, Springfield, Cupar.

PORTSMOUTH: ROYAL PORTSMOUTH HOSPITAL.—*Honorary Assistant Surgeon:* John D. Youngshand, F.R.C.S. *Honorary Assistant Anaesthetist:* P. R. Bromage, M.B., B.S., D.A., Paul Merlin, M.B., Ch.B., D.A.

STREET, F. N., M.B., F.R.C.S., Resident Surgical Officer, Hospital for Sick Children, Great Ormond Street, London, W.C.

BIRTHS, MARRIAGES, AND DEATHS

BIRTHS

Bickford.—On Dec. 25, 1947, at the Mayo Clinic, U.S.A., to Dr. Joyce Bickford (née Davies), wife of Dr. R. G. Bickford, a son.

Brown.—On Jan. 7, 1948, at Edgbaston Maternity Home, Birmingham, to Jean, wife of Dr. R. J. K. Brown, a daughter.

Fraser.—On Jan. 7, 1948, to Dr. and Mrs. R. J. A. Fraser (née Dr. Mary E. Chalmers), 77, Anderson Drive, Aberdeen, a son.

Kay.—On Jan. 11, 1948, at Claremont Nursing Home, Glasgow, to Janice and Drew Kay, M.D., F.R.C.S.Ed., a daughter.

Oakes.—On Jan. 13, 1948, at Southmead Hospital, Bristol, to Jean and Henry Oakes, a son.

Roberts.—On Dec. 31, 1947, at the Queen Elizabeth Hospital, Birmingham, to Margaret (née Holloway), wife of Dr. Keith D. Roberts, a daughter—Meryl Elizabeth.

Thompson.—On Jan. 7, 1948, at Woodfield Nursing Home, Oldham, to Doreen (née Bickford), wife of Dr. John Thompson, a second child—Joanna Mary.

MARRIAGE

Cox—Monaghan.—On Jan. 14, 1948, at Merton Mowbray, John Cox, M.B., D.R.C.O.G. and Irene Monaghan, M.B., Ch.B.

DEATHS

Anderson.—On Jan. 10, 1948, at 74, Lower Baggot Street, Dublin, Joseph Barcroft Anderson, M.D.

Beesley.—On Jan. 16, 1948, at 7, Lion House, Exmouth, Clarence Beesley, L.R.C.P.&S.Ed.

Bell.—On Jan. 11, 1948, at "Edzell," Lundin Links, Fife, James Bett Bell, M.B., Ch.B.

Bevis.—On Jan. 9, 1948, Harold Bevis, M.R.C.S., L.R.C.P., of Cromwell House, Haydon Park Road, Wimbledon, S.W., aged 64.

Colmer.—On Jan. 10, 1948, at 8, Junction Road, Oldfield Park, Bath, Vylian Colmer, M.R.C.S., L.R.C.P., aged 65.

Downes.—On Jan. 12, 1948, Mary Mounsey Downes, M.B., Ch.B., of Elgar Avenue, Tolworth, Surbiton, Surrey, aged 53.

Duncan.—On Jan. 18, 1948, at Manchester Royal Infirmary, Helen Winifred Duncan, M.D., M.R.C.P., of 11 Wennington Road, Southport.

Glenny.—On Jan. 7, 1948, at Merham Terrace, Warrenpoint, Co. Down, Ireland, William Charles Watson Glenny, L.R.C.P.&S.I. and L.M., aged 72.

Greathead.—On Jan. 13, 1948, at Durban, South Africa, Edward Rivers Greathead, M.R.C.S., L.R.C.P., late of St. Albans, Herts.

Lewis-Hoyd.—On Jan. 12, 1948, at Towy, N. Wales, Evan Lewis-Hoyd, M.R.C.S., L.R.C.P., aged 75.

McMillan.—At Shotts, Lanarkshire, John McMillan, M.B., Ch.B.

Mannell.—On Jan. 18, 1948, at 6, Courtfield Road, London, S.W., Debonnaire Frederick Mannell, M.R.C.S., L.R.C.P.

Murphy.—On Jan. 17, 1948, at 2, Ethelbert Road, Canterbury, Charles Edward Murphy, F.R.C.S.I., aged 77.

Oldmeadow.—On Jan. 14, 1948, at Bramley, Hampshire, Lloyd John Hollis Oldmeadow, M.D., F.R.C.S.Ed., late of Kington, Warwickshire.

Plumbly.—On Jan. 12, 1948, George Lewis Spurrell Plumbly, M.B., B.S., of Harvey House, Watton, Thetford, Norfolk, aged 44.

Reardon.—On Jan. 11, 1948, at 88, Blackford Avenue, Edinburgh, James Clement Purcell Reardon, L.R.C.P.&S.Ed.

Staley.—On Jan. 11, 1948, at 70, Barton Road, Barton-upon-Irwell, Lancs, Robert James Staley, M.B., Ch.B., aged 56.

Thomas.—At Brynmawr, Breconshire, John Lewis Thomas, M.D., aged 85.

Watson.—On Jan. 12, 1948, at Gibraltar, William Bertram Watson, M.D., of Harrogate, aged 70. Funeral at Gibraltar Jan. 14. Memorial service at St. Peter's Church, Harrogate, Jan. 21, 11.15 a.m.

Any Questions?

Correspondents should give their names and addresses (not for publication) and include all relevant details in their questions, which should be typed. We publish here a selection of those questions and answers which seem to be of general interest.

Vitamin D for Chilblains

Q.—*Very large doses of vitamin D₂ (up to half a million international units at weekly intervals) have been recommended as a preventive of chilblains. Is there any risk of heavy deposition of calcium in the tissues if old people take the vitamin in such amounts?*

A.—According to the most recent evidence vitamin D is ineffective in both the prevention and treatment of chilblains (*Lancet*, 1947, 2, 794). It should never be used for this purpose, as it can be toxic if given in the high doses often recommended. Half a million units at weekly intervals would probably not produce toxic effects. Many patients apparently tolerate 150,000 units daily over a period without any harmful effects, although toxic effects have been reported from doses of 100,000 to 200,000 units daily. Doses of more than 150,000 units daily are potentially dangerous. The chief dangers of overdosage with vitamin D are metastatic calcification, particularly in the kidneys and blood vessels, and renal failure, which may be irreversible. Early symptoms of intolerance are nausea, vomiting, headache, tiredness, muscular weakness, and polyuria.

Prescribing Dangerous Drugs

Q.—*In some hospitals the procedure adopted for prescribing dangerous drugs is for the resident medical officer or consultant to state the strength of the dangerous drug required and to initial the prescription. In the Dangerous Drugs Regulations it is stated that the prescription should be signed by the responsible medical officer. Does this mean that initialling of the prescription is inadequate?*

A.—The law relating to this subject is well set out in Speller's *Law Relating to Hospitals*, pp. 167–74, which would well repay study by any member of a hospital staff who may have occasion to handle these drugs. The regulations made under the Dangerous Drugs Acts, 1920–5, were modified by the Dangerous Drugs (Hospital General Exemption) Order, 1924, which provides that the initials only need be added to a prescription for such drugs, if written by a properly authorized member of the staff on a printed prescription form issued by the hospital. If a blank sheet of paper is used it must bear the full signature of the prescriber, together with the other particulars required under the D.D.A. regulations. The prescription must be dated, and must bear the name of the patient who is to receive the drugs (or his registered number; this applies particularly to patients attending a clinic for venereal disease, who may be identified only by such a number).

Dangerous drugs may also lawfully be supplied by a hospital dispenser on the requisition of a sister in charge of a ward, for the purpose of replenishing her stock, to be used in accordance with the orders of the doctor or dental surgeon concerned; there is no definition of the qualifications of the sister (or there is of the hospital dispenser) under these regulations, but it is probable that she must be a State registered nurse. Her requisition must be filed in the dispensary and she must keep a copy of it.

Industrial Hazard of Sodium Chromate

Q.—*What will be the effect, if any, on the health of workers using returned empty biscuit tins with a solution of sodium chromate in 1946 in a detergent solution of 0.8% trisodium phosphate plus 1.6% metasilicate at 180° F.?* The tins are subsequently removed with hot water.

A.—Dermatitis of the hands and forearms, if exposed, and possibly irritation of the nasal mucosa, may occur. It is probable that the solution of sodium chromate in the bath is very concentrated, but even if the solution is diluted, there is a possibility of irritation of the skin if the bath is not carried into the atmosphere. It

is now known that the characteristic effects of the bichromates and chromic acid may also be produced by monochromates. Trisodium phosphate with sodium metasilicate may be expected to exercise its detergent effect also on the exposed skin of cleaners, and, even though the bath contained nothing more than heated water, constant immersion of the unprotected skin over long periods might be expected to have a deleterious macerating effect.

Insomnia and Loss of Memory

Q.—*What are the likely causes of insomnia and loss of memory for current events and duties in a woman in the early forties? What investigations are required?*

A.—Insomnia might be due to actual bodily illness or to emotional disturbances. Loss of memory for current events suggests an organic factor, and, if it is of severe degree and of any permanence, would be classifiable as dementia. In this case a cerebral lesion would have to be looked for. Its nature might be of many different kinds, including chronic alcoholism, cerebral syphilis, cerebral tumour, and the presenile dementias. The investigations required are along the usual neurological and psychiatric lines, and directed in the first place towards establishing a real impairment of memory. It is quite probable, however, that memory itself is not impaired, although the patient herself or her relatives feel that it is. Complaints of a subjective experience of memory failure are common in psychiatric states without organic lesion, especially in mild depressive conditions. It is possible, that the patient is suffering from a neurotic state or a mild involutional depression.

Wax in the Ears

Q.—*Wax accumulating in the outer part of the auditory canal impairs already defective hearing. Can anything be done to prevent this?*

A.—If there is an underlying dermatitis of the external auditory meatus which is causing excessive secretion or abnormal consistency of the wax, then treatment of the skin affection should help. Apart from this the best treatment is to use drops, such as olive oil, which will render the wax as fluid as possible.

Pain on Cutting Nails

Q.—*My niece, aged 14 years, causes herself pain when cutting her nails with scissors, and for some days afterwards she feels the nail edges raw and painful. There is no question of any functional cause. It is a case of "Let me cut my nails and I cause pain." The only treatment I can think of is to apply some anaesthetizing ointment afterwards. What do you suggest?*

A.—Pain on cutting the nails is not likely to have any anatomical basis in fact and is likely to be psychogenic in origin. It would be interesting to know how long this symptom has existed. Ruling out mental deficiency, this appears to be a case of masochism, which is usually defined as sexual pleasure in having pain inflicted on one. Dependence and sensuous passivity are normal characteristics of the infant; and also in the sexual relations of the woman, who desires to be overmastered, even to the extent of being hurt—a relic of "marriage by capture." The perverted tendency of which this seems to be a case comes about when sexual feelings are aroused in the child in association with the infliction of pain. The commonest instance is where a child sexually stimulates itself and is smacked while experiencing such feelings. The sexuality in such a case not only is associated with the smacking but is repressed by it, so that it is fixated and arrested in that form and may not develop into normal adult sexuality. The specific cause in this case, which it is necessary to investigate for radical cure, would have to be discovered by "play therapy" at the hands of an expert. If expert advice is not available, then so far as possible the child should be given counter-attractions at such times, in the hope of diverting her interest. Many such perversities disappear when more adult sexuality begins to appear at puberty, and in this case the girl may grow out of it. On the other hand, it is often found that such perversities begin to show themselves only at puberty.

when the sex feelings are beginning to be aroused, and therefore precipitate the unconscious conflict already mentioned. Treatment of the end-result by antiseptics is of course indicated.

Lochial Discharge

Q.—*Why is it that, whereas before the war the lochia become yellow or clear by the eighth or tenth day, nowadays the discharge remains bloodstained almost without exception for anything up to three weeks? What treatment is advised?*

A.—The old view that the lochial discharge normally ceases to be bloodstained by the tenth day is not true, and most modern textbooks comment on this. The bleeding may clear up temporarily while the woman is in bed, but almost always comes on again when she becomes more active, and then continues on and off for varying periods of time. The average is probably about three weeks from the time of delivery, but slight intermittent bleeding persisting for five to six weeks is by no means rare and is not necessarily pathological. These observations apply to the pre-war period as well as the present, and there has not been any significant alteration. No treatment is necessary unless the bleeding is heavy.

Toxic Effects of Formalin

Q.—*What are the possible effects of continued inhalation of small concentrations of formalin? The mother of a family living in close proximity to a pathological laboratory which continuously reeks of formalin complains that her 3-year-old son regularly wakes pale and querulous after going to bed quite cheerful and sleeping for a period of from ten to twelve hours. She suspects that this may be due to the presence of formalin in the atmosphere, as the child's bedroom is immediately above the factory. Is this likely?*

A.—Formaldehyde is an irritant gas and a protoplasmic poison. Its most noticeable effect is irritation of the mucous membranes and of the skin. Brunnthaler (*Occupation and Health*, I.L.O., Geneva, 1930, p. 809), in his position as Keeper of the Botanical Institute in Vienna, studied the effects on himself of the prolonged use of formalin. These effects included acute catarrh of the nose and eyes, chronic pharyngitis and laryngitis, and acute nervous manifestations. The latter are thought to be very rare, and it is suggested that other explanations for the condition described above in the little boy should first be excluded.

Skin Graft for Leg Ulcer

Q.—*A woman aged 56 has a leg ulcer of twenty years' duration; it measures 4 by 6 inches (10 by 15 cm.). There is a watery odourless discharge; the edges are thick and sclerotic. How should this be prepared for skin-grafting and how should the graft be made?*

A.—The problem in such leg ulcers is to achieve a clean vascular base free from scar tissue. Preliminary rest in bed, with four-hourly eusol packs, is helpful; but careful excision of the area and its base at operation is essential. An alternative regimen involves the Bunyan-Stannard envelope routine. Thin razor grafts "take" best, and it may be safer to use them in "postage-stamp" form. It is assumed that there are no associated varicose veins.

Calcium Metabolism in Osteitis Deformans

Q.—*Hos recent work on calcium metabolism thrown any light on the treatment of Poyet's disease (osteitis deformans)?*

A.—The answer to this question must unfortunately be in the negative. The general consensus is that no convincing alleviation of symptoms can be consistently obtained by treatment based on any particular concept of the role of calcium metabolism in this disease. It has of course been claimed by many workers that osteitis deformans is a manifestation of hyperparathyroidism, though the cause of the alleged hyperparathyroidism has not been demonstrated. A recent theory has been advanced by Helfet, who suggests that the fundamental cause is a retention of phosphates in the body and that this stimulates a compensatory hyperparathyroidism. He has accordingly advocated treatment by the administration of small doses of aluminium acetate, which inhibits the absorption of

phosphorus from the intestine by combining with it to form insoluble aluminium phosphate. This is excreted unchanged by the bowel. Although promising results have been claimed from this treatment in a small number of patients it is impossible to contrast them with suitable controls because of individual variations in the natural course of the disease. Much further evidence is therefore required before the merits of this line of treatment can be fully evaluated.

Relaxation of Bronchial Spasm

Q.—*Has 50% ether in 50% olive oil given as a retention enema any effect on bronchial spasm and on tenacious mucus? What should be the dose and how often may it be repeated?*

A.—If ether is absorbed from a retention enema of this composition in sufficient amount to relax bronchial spasm it would certainly intoxicate the patient. Such a treatment should not be used, as it is most unlikely to be effective.

Whalemeat and Iodine

Q.—*It is suggested that whalemeat is probably rich in organic iodides, and therefore should be a valuable food in chronic nervous diseases. Is there any foundation for this idea?*

A.—It appears that no estimation of iodine in whalemeat has been made. It seems likely, however, that whalemeat does contain relatively large amounts of iodine, like other foods which come out of the sea. It would be difficult for the whale to avoid being iodine-rich. It is impossible to give a precise answer to the question about chronic nervous diseases. It seems to be true that a good many people are benefited by the administration of iodine. Some think that the benefit of cod-liver oil is due in part at least to the iodine it contains. It is probable that many people eat a diet which is for them partly deficient in iodine, and this accounts for the improvement they observe when iodides are taken. Iodine is, of course, essential for the thyroid gland. In many conditions, however, sodium iodide administered without precise reason seems to be beneficial; amounts such as 5 gr. (0.32 g.) daily by mouth are usual.

White of Egg

Q.—*Am I right in thinking that raw white of egg is not digested and absorbed, and that consequently the giving of albumen water is pointless?*

A.—Raw white egg is digestible and readily absorbed. The statement that it is not digested has as little convincing experimental backing as the even more frequently repeated assertion that "lightly cooked" eggs are much more easily digested than the boiled article. Overheating—for example, frying with smoking fat—can, however, greatly decrease the digestibility of egg white.

Black Tongue

Q.—*What is "black tongue"? Is it of any significance in an otherwise healthy individual, and can you suggest any treatment?*

A.—Black tongue is a harmless condition which gives rise to no symptoms. It is usually due to enlargement and hyperkeratosis of the filiform papillae upon which becomes engrafted an infection with a mould, most often *Aspergillus niger*. In many instances the condition disappears spontaneously in a few months. Treatment is not very satisfactory, but scraping under local surface anaesthesia followed by painting of the area with 2% iodine may be effective. Sometimes weak applications of acetic or lactic acid cures the condition: stubborn cases have yielded to irradiation.

Injection of Varicose Veins

Q.—*When I inject superficial varicose veins of the leg a marked discoloration of the vein appears. It persists for a long time and is ugly. There is no extravasation and the discoloration is definitely along the course of the vein.*

A.—In some dark-skinned persons there is a tendency to a permanent brown discoloration of the skin over the thrombosed veins. This is a source of great annoyance to the female

patient. It can be prevented by making "cigarette" rolls of elastoplast, sticking these along the course of the injected vein, and then applying firm elastoplast bandages from toes to thighs for seven to fourteen days. The two walls of the veins are thus brought into contact, a clot does not form, and the exuded blood pigments do not discolour the skin.

Burnt Sugar and Allergy

Q.—I heard the instructor of a cookery class warn his pupils that the common Continental custom of burning sugar for a base for sauces is liable to produce allergic rashes in some people. Is this suggestion likely or unlikely?

A.—The suggestion is possible, but further observations and experiments would be necessary to substantiate it. Although some patients suspect sugar as the cause of their allergies, this is rarely if ever true. Rowe has suggested that the possibility of sensitization to the allergens in brown sugar or molasses should be kept in mind (Rowe, A. H., *Food Allergy*, 1937, p. 607).

NOTES AND COMMENTS

Enuresis in Young Adults.—Dr. R. F. KAYE WEBSTER (Monkseaton, Northumberland) writes: In four cases of this condition—i.e., chronic bed-wetting—I have found the use of nicotinic acid 50 mg. t.d.s. invaluable. In fact since I started this treatment with these cases I have not found it fail. The worst case was a young man of 30 who had had the condition since a boy; all other treatment failed. With nicotinic acid he was immediately cured. This was essential for him before he married. He has been married a year and is quite happy now. During this year I gave him a small tablet of phenobarbitone in lieu of nicotinic acid to see if cure was imaginary; he came back in a week with condition returned. When nicotinic acid was again given he immediately settled down. My youngest patient is a girl of 11 who has always bed-wetted nightly, sometimes two or three times a night. With 25 mg. of nicotinic acid t.d.s. she stopped from the first day's treatment and has remained cured so far. I am not prepared to analyse the chemistry of the treatment but pass it on as a useful tip, knowing particularly how embarrassing it can be for young men about to marry and young men joining the Forces, with the old-fashioned guard-room routine.

Constipation in an Infant.—Dr. JOYCE E. MARSHALL (London, N.W.) writes: With reference to the question and answer on constipation in an infant (Nov. 29, 1947, p. 896), exception might be taken to the treatment suggested on the following grounds. It is a physiologically unsound approach. For example, the nature of the baby's diet is not considered, whether breast or bottle, fluid intake, and supplements. It is psychologically unsound. Considerable fear may be caused in a normal child by a daily painful stimulus to a highly sensitive area of the body, such as stretching a sphincter or applying an irritant. Cases have been published which show that such treatment, also the use of enemata and suppositories in childhood, may bear a direct relationship to serious disorders in emotional development manifest in later life. In infant-welfare work it is, in my experience, a common feature of this age period that children show a change to infrequent bowel actions for a period, which is usually terminated when mixed feeding is being introduced later. Over-zealous toilet training from early infancy in some cases seems to result in a resistance in the child shown by his withholding his stools for periods, and this may exaggerate the common trend to less frequent bowel actions in this period. In the case described the history of the previous digestive disorder of four weeks' duration possibly resulted in diminished bowel tone, which would be a contributing factor.

Judicial Hanging.—A retired senior medical officer of the English Prison Service writes: From time to time rather absurd statements appear in your columns about judicial hanging. I was thirty years in the English Prison Service and can say that the statements by Dr. J. R. V. Foxton (Dec. 13, 1947, p. 986), especially those attributed to Prof. Fredrick Wood Jones, are without foundation. A carefully worked-out "drop" is used on all occasions. All the cases in which I was present (23 in number) had a post-mortem examination at least partial only, but latterly a full post-mortem examination which showed in each case fracture dislocation of the cervical vertebra with rupture of the cord. In every case the body was placed at the angle of the jaw.

Dr. Foxton's Remarks.—Dr. J. R. V. Foxton (London, N.W.) writes: In your issue of Dec. 13, 1947, p. 986, my remarks on judicial hanging were misquoted. I stated that in 1944, 1945, and 1946, together with 1947, I attended the execution of six criminals in each case. Some

hours after death I performed a necropsy, and in each case the second cervical vertebra was fractured. Definite preparations based upon experience are made for each execution—the length of the drop varying with the weight of the victim, and the gauge and quality of the rope definitely assessed.

Food Allergy.—Dr. JOHN FREEMAN (London, W.) writes: With regard to the courteous reply by your adviser (Dec. 13, 1947, p. 986) I nevertheless stick to my guns. My co-workers and I have usually found test feeding to be unreliable: it is far too difficult to make in this way anything like a crucial experiment. On the other hand, skin testings with egg protein are reliable—so far as they go, but no further. I agree emphatically with your adviser that they are often misleading, but that is because of faulty interpretation; a definite positive does not mean necessarily that there is an important causal relationship between, say, egg protein and the disease in question. An egg sensitiveness can most certainly be removed by inoculation treatment, if thought worth while; and this usually causes less hospitalization than careful feeding experiments would entail.

Chilblain of the Nose.—Dr. J. F. LYONS (Almondsbury, nr Bristol) writes: With reference to your correspondent's question (Dec. 20, 1947, p. 1017) I suggest that he should apply a solution of either 1 or 2% picric acid to the parts two or three times daily for a few days. I have found this treatment very satisfactory in relieving the tension and irritation in chilblains of the hands and feet.

Ringworm of Scalp.—Col. W. H. CRICHTON, C.I.E., I.M.S.(ret.) writes from Sittingbourne, Kent: Dr. I. M. Scott's comment (Dec. 2, 1947, p. 1066) on my letter on the treatment of an outbreak of ringworm of the scalp in North Devon calls for a clarification if a useful measure of treatment is not to be lost to the profession. In the first place it should be understood that the form of treatment I employed—namely, depilation with a saturated solution of KMnO₄ applied for 14 days followed by applications of Whitfield's ointment—was one recommended by an experienced dermatologist as an alternative to x-ray treatment, which is often extremely difficult or impossible to obtain. Secondly, my cases in the North Devon outbreak were all definitely proved to have been infected with *Microsporum felinum*, which undoubtedly responded to the treatment to the extent of cure if this can be measured by subsequent observation over a period of several months and by the fact that specimens of stumps pulled out after completion of the course of treatment were found negative by the county laboratory. To my knowledge there has been no recurrence. Thirdly, I have been advised that infections with *M. felinum* are much more susceptible to treatment than those of *M. audouini*, and the success achieved in the North Devon outbreak may therefore be attributed to this fact. On the other hand I have hitherto found no evidence that this form of treatment has been tried in cases of proved *M. audouini* infection and, if so, with what result. Lastly, it should be noted that in several cases the course of treatment had to be repeated once and even twice before a negative laboratory result was finally obtained. I do not know if Dr. Scott has actually had any experience of this form of treatment for tinea capitis, but it certainly would not be fair to condemn it without trial.

Dr. ROBERT ANDERSON (Erdington, Birmingham) writes: Dr. I. M. Scott (Dec. 27, 1947, p. 1066) states that there is an effective vehicle to carry a fungicide inside the hair shaft. I think glacial acetic acid acts in this way. A layman gave me the method and I found it always successful. The acid is applied with a glass rod or cotton-wool on a probe. Immediately a whitene appears a pad of cotton-wool squeezed out of very hot water is applied. That removes the stinging of the acid. Next day the hair can be easily depilated.

In 1910 I attended a family of five children—two girls and three boys—who were all suffering from tinea. I had the boys shaved but only had the girls' hair cut round the affected areas. The girls had only one patch each, but in the case of the boys the disease was scattered all over their scalps. I found the hairs came out quite easily without breaking. It took me a month or six weeks to finish the depilation.

All communications with regard to editorial business should be addressed to THE EDITOR, BRITISH MEDICAL JOURNAL, B.M.A. HOUSE, TAVISTOCK SQUARE, LONDON, W.C.1. TELEPHONE: EUSTON 2111. TELEGRAMS: *Alldred Westcott, London*. ORIGINAL ARTICLES AND LETTERS forwarded for publication are understood to be offered to the *British Medical Journal* unless the contrary be stated.

Authors desiring REPRINTS should communicate with the Publishing Manager, B.M.A. House, Tavistock Square, W.C.1, on receipt of proofs. Authors overseas should indicate on MSS. if reprints are required, as proofs are sent abroad.

SUPPLEMENT TO THE BRITISH MEDICAL JOURNAL

LONDON, SATURDAY JANUARY 24 1948

INSURANCE ACTS COMMITTEE

The following resolution was passed at a special meeting of the Insurance Acts Committee on Jan. 15.

"The Insurance Acts Committee, representing every insurance practitioner in the country, owes it to its constituents to make abundantly plain exactly where it stands on the grave issue which now confronts insurance practitioners, as it does other members of the profession. Fully conscious of all the implications, the Committee condemns the National Health Service Act, 1946, in its present form as contrary to the best interests of the public and advises insurance practitioners firmly to reject it in the forthcoming plebiscite."

The meeting was called to consider the situation in relation to the National Health Service in so far as it affects insurance practitioners, including the desirability of convening a Special Conference of representatives of Local Medical and Panel Committees. Dr. E. A. Gregg presided, and there was a full attendance.

The Chairman of Council, Dr. Dain, said that after the result of the plebiscite was known there would be another Special Representative Meeting, which had been fixed for March 17, and the Committee might think it desirable to hold a Special Panel Conference at about the time of that meeting. Should there be an adequate majority against acceptance of service a good deal of organization work would have to be done, particularly in panel committees.

The Committee decided that a Special Panel Conference should be called for March 16.

The question was then debated at length whether the Insurance Acts Committee as such should give a lead to insurance practitioners as distinct from the lead which the Council is giving to the entire profession. The Secretary detailed the various documents which would be sent out to members of the profession before the plebiscite. Although some members of the Committee desired that a special communication should be sent individually to insurance practitioners, they recognized that this would impose an addition to the heavy work at present being done at Headquarters, making it virtually a physical impossibility. It was suggested that any manifesto of this kind might be sent to local medical and panel committees and distributed locally, but in the end the Committee agreed that the manifesto, addressed specially to insurance practitioners, should be included in the second set of documents to be sent out to the whole profession.

Discussion then took place on the nature of the statement to be made. Some members of the Committee were anxious that it should be a detailed statement of objection to the Minister's contentions, but here again it was pointed out that such detail was covered by the documents already prepared. The resolution set out above was thereupon carried, and forty members of the Committee present signed their names to the document. Two members abstained from signing, saying that they wished to leave the vote in the plebiscite to the free deliberation of the individual, uninfluenced by any lead from the centre.

Purchase and Sale of Practices

Following a resolution of the last Annual Conference, the Committee had asked one of its members, Dr. F. M. Rose, to prepare a memorandum on the possibility of establishing a special fund to finance the purchase and sale of practices, the scheme being so designed as to eliminate the difficulties and objections experienced in the past. Dr. Rose brought forward

a memorandum in which the whole position was examined. One of his recommendations was that the purchase price of practices should be such that it would be possible to redeem the debt out of income in ten years or less. Dr. Rose considered that the purchase price, in particular of smaller practices, had been too high in the past, and that if the profession valued the retention of goodwill it should be prepared to make a sacrifice by a reduction in sale price. If 1½ years' purchase was regarded as a maximum for higher-income practices, few doctors, in view of the increase in income of most practices since 1939, would receive less than the 1939 value at the rates accepted then. This was challenged by one member of the Committee, who contended that the devaluation of the pound made it not sensible to talk about cutting the value of capital.

Dr. Rose also suggested the setting up of a central agency under medical control, replacing all existing agencies, to give advice on matters relating to practice transfers, partnerships, and assistantships, to furnish particulars of all vacancies, to arrange loans if financial arrangements were desired, and to supervise legal agreements.

The Chairman said that their minds were very much occupied with many matters which made it difficult at the moment to give the attention it deserved to this complex question. It was accordingly deferred to the next meeting with a view to the setting up of a section of the Committee to proceed further with the question.

Other Business

Dr. Sutherland, chairman of a subcommittee which has been examining the draft medical card with a view to discussing with the Ministry such modifications as were considered desirable, reported a number of detailed recommendations which were provisionally approved; the subcommittee has not yet finished its work. Dr. Pridham, as chairman of the Organization Committee, reported that that body was of opinion that it was premature to consider any changes in the constitutional powers of the Insurance Acts Committee and the General Practice Committee, though with the shaping of events such consideration may soon become necessary.

It was reported that a reply had been received from the Ministry to the Committee's application in September last for an increase in the capitation fee for emergency drugs and appliances. The Minister had decided that the existing capitation fee payable to insurance practitioners for the provision of drugs and dressings before a supply could be conveniently obtained otherwise under the medical benefit regulations should be doubled in all areas, with effect from Oct. 1, 1947. A circular on the subject is shortly to be issued.

TRADE UNION MEMBERSHIP

The following is a list of local authorities which are understood to require employees to be members of a trade union or other organization:

County Borough Councils.—Gateshead.

Metropolitan Borough Councils.—Fulham, Hackney, Poplar.

Non-County Borough Councils.—Dartford, Leyton, Radcliffe (limited to future appointments), Tottenham, WallSEND.

Urban District Councils.—Denton, Droylsden, Houghton-le-Spring, Huyton-with-Roby, Portslade, Redditch (restricted to new appointments), Stanley (Co. Durham), Tyldesley.

Scottish Burghs.—Motherwell and Wishaw.

HEARD AT HEADQUARTERS

A Good Day's Work

The Special Representative Meeting was a businesslike affair, without any oratorical embroidery. Representatives seemed to feel that the time for talk had passed. The purpose of the meeting was to secure the most clear and unambiguous expression of opinion in the plebiscite. The absence of the Chairman of Council at the beginning caused some concern, but he appeared within half an hour and explained that the train from Birmingham, desiring no doubt to celebrate its recent nationalization, had taken a roundabout, erratic, and unscheduled course to Euston, arriving an hour late. The serious part of the business over, Mr. Lawrence Abel again obliged with some nursery rhymes adapted to the occasion.

Form Filling

A very sensible remark was made by the opener of the discussion at a meeting of the Royal Statistical Society the other day—Mr. H. Cotton, of the Nuffield Bureau at Oxford. He was talking about the collection of morbidity data from hospitals, but his point has a wider connotation. He deprecated the excessive use of questionnaires and "quiz" forms intended to guarantee the collection of all possible relevant information. A thing to be particularly resisted in drawing up a question form, he said, is to collect something interesting but not vital simply because the opportunity to do so is there. A form which requires a busy doctor to enter particulars which can be obtained as easily and as accurately by a clerk is not a sensible form. The doctor should be asked to complete only that part of a form which cannot be completed by anybody else, and if he has already given the needed information in some other document he should not be asked to repeat it. Mr. Cotton was all against omnibus forms which provide for details not generally applicable, or at any rate not applicable to a substantial proportion of all cases.

Transatlantic Glimpses

An American doctor seems to be asking rather a lot of human nature. He says that it is his custom to send a special Christmas greeting to patients who have owed him a guinea or less for over a year. He sends them a receipted account. Often, he says, they return the greeting, including payment in full of the outstanding debt.

An Army medical officer had a corporal in his charge who was suffering from bronchopneumonia. He sent a telegram to the corporal's mother, telling her of her son's serious illness but assuring her that he was receiving all possible attention. Next day the corporal himself received a telegram from his mother: "Let me know how you are getting on. If you die, have body shipped home."

Ready for the Post

Headquarters just now are asking big things from the General Post Office. This week a detailed analysis of the Minister's reply, the pictorial folder already referred to in these notes, and the reprint of the leading article in the *Journal* of Jan. 17 have been sent out to all members of the profession. Next week there will go out two more documents. It is simple to say, "Let it be circulated to all members of the profession," but few have any idea of the Herculean labour behind such an instruction. Including the sending-out of the Negotiating Committee's case and the Minister's reply, the two circularizations just mentioned, and finally the plebiscite forms, something like 250,000 envelopes will have been addressed. The cost in postage, if we assume a penny stamp on each envelope, is slight, but the bigger thing is the amount of work involved in the careful addressing and dispatching of this record.

RETURN TO PRACTICE

Mr. R. Vaughan, M.B., B.Ch., has returned to practice at Woodley, near Reading.

Association Notices

SPECIAL MEETING

Consultants and specialists will meet to discuss the National Health Service Act and the plebiscite at B.M.A. House, Tavistock Square, W.C.1, at 8.30 p.m. on Tuesday, Jan. 27. *Chairman*.—Mr. A. M. A. Moore, Chairman of Consultants and Specialists Committee. *Speakers*.—The Right Honourable Lord Horder, Dr. Geoffrey Marshall, Mr. A. Dickson Wright, Mr. N. Ross Smith.

Branch and Division Meetings to be Held

BOURNEMOUTH DIVISION.—At Boscombe Hospital, Friday, Jan. 23, 8.15 p.m. Report of Representatives to Special Representative Meeting, Jan. 8; National Health Service Act.—The Plebiscite. Address by Dr. D. P. Stevenson, Assistant and Regional Secretary, B.M.A., followed by questions and discussion.

DERBY DIVISION.—At Derbyshire Royal Infirmary, Tuesday, Jan. 27, 7.30 p.m. Mr. A. G. G. Melville: Demonstration of Results of Radiotherapy; 8.15 p.m., Mr. J. R. Ratcliffe: Cancer of Stomach, Colon and Rectum.

METROPOLITAN COUNTIES BRANCH.—At B.M.A. House, Tavistock Square, London, W.C., Tuesday, Feb. 3, 5 p.m. Lecture to Senior students and newly qualified practitioners by Mr. Claud Mullins: "The Court and the Doctor."

H.M. Forces Appointments

ARMY

Colonel Q. V. B. Wallace, C.B.E., M.C., late R.A.M.C., has been retained on the Active List supernumerary to Establishment.

Colonel F. G. Flood, O.B.E., M.C., late R.A.M.C., has retired on retired pay.

ROYAL ARMY MEDICAL CORPS

Captain (War Substantive Major) E. L. O. Hood to be Major. Captain E. A. Balls, from R.A.M.C., Emergency Commission, has been granted a Short Service Commission in the rank of Captain.

LAND FORCES: EMERGENCY COMMISSIONS

ROYAL ARMY MEDICAL CORPS

War Substantive Captains S. Hickling, G. H. Robertson, and K. M. Robertson have relinquished their commissions and have been granted the honorary rank of Major.

Short Service Commission, Specialist.—War Substantive Captain R. Schneider has relinquished his commission and has been granted the honorary rank of Major. F. G. W. Marson to be Lieutenant.

War Substantive Captains F. O'N. Danni and D. C. Roberts have relinquished their commissions on account of disability and have been granted the honorary rank of Captain.

Lieutenants J. R. G. Edwards, J. J. Gilleran, A. G. M. Watt, J. W. Aalders, E. L. Arnold, M. A. Cooke, J. W. E. Dunphy, C. L. Joiner, C. I. Levene, E. R. O. E. Spearing, W. O. Spence, and R. P. Harwood to be Captains.

INDIAN MEDICAL SERVICE

Lieutenant-Colonel D. P. Lambert has retired and has been granted the honorary rank of Colonel.

Lieutenant-Colonel G. F. Taylor has retired on account of ill-health and has been granted the honorary rank of Colonel.

Lieutenant-Colonel R. K. Tandon to be Colonel.

Lieutenant-Colonel P. M. Ania has retired.

Major C. J. H. Brink has retired receiving a gratuity.

COLONIAL MEDICAL SERVICE

The following appointments have been announced: E. W. Brett, L.R.C.S., Lady Medical Officer, Nigeria; T. W. Buckley, M.B., B.Ch., Travelling Medical Officer, Sarawak; R. C. Drummond, M.B., Ch.B., Medical Officer of Health, Tanganyika; G. M. Gorrie, M.B., Ch.B., and T. L. W. McCullagh, M.C., M.B., B.S., Medical Officers, Kenya; R. M. Irwin, M.B., Ch.B., Medical Officer, Fiji; J. Toner, M.B., B.Ch., Medical Officer, Nigeria; F. W. M. Lamb, M.B., Pathologist, Health Department, Palestine; F. R. S. Kellett, M.B., Medical Officer, St. Lucia, Windward Islands; L. Winkellaken, M.D., Supernumerary Medical Officer, Leeward Islands; L. Wiuic, M.D., Medical Officer, Gold Coast; R. C. Burgess, M.B., Ch.B., Senior Nutrition Officer, Malaya; N. Chikou, B.Ch., D.T.M.&H., Senior Medical Officer, Tanganyika; G. D. Drury, M.R.C.S., L.R.C.P., Senior Medical Officer, Labour Department, Kenya; A. M. Fleming, M.B., B.S., R. McFiggans, M.B., Ch.B., and H. N. Turner, M.B., B.Ch., Senior Medical Officers, Kenya; A. H. Lowther, M.B., Ch.B., Specialist, Grade B.

OUR FOUNDERS AND BENEFACTORS*

BY

CHARLES ERNEST LAKIN, M.D., F.R.C.P., F.R.C.S.

Consulting Physician to the Middlesex Hospital, London

In bringing our Founders and Benefactors to your notice—and it is the early benefactors I am concerned with in particular—I do so with no little trepidation. Historical documents so rarely enshrine those traits of character, demeanour, and bearing which are so essential if a lively picture is to be presented and if the recital is to be more than a mere catalogue of benefactions and achievement.

This is a difficulty I can scarcely surmount. Not that there is any lack of material; indeed, Professor A. F. Pollard, perhaps the greatest student of the period, has written: "The materials for sixteenth-century history are so vast that no one can hope to master them all in the allotted span of human life."

However much Fellows will wish to emphasize the fact that our College is a Royal foundation, all will agree that its inception was due to Thomas Linacre, one of the King's physicians. Many are the references to him and his friends in the State Papers of Henry VIII, published by the authority of His Majesty's Commission in 1830-52; but, so far as I have been able to ascertain, only one Life of Thomas Linacre has been written. The author of the biography was Dr. John Noble Johnson, a Fellow of this College, Goulstonian Lecturer, Censor and Physician to the Westminster Hospital.

Linacre's Student Days

Thomas Linacre, so far as can be ascertained, was born in Canterbury in the year 1460. He attended the school of the Monastery of Christchurch, Canterbury, then presided over by his kinsman, William Tilly of Selling. It is curious that Canterbury should have provided the early education of both our Founder, Thomas Linacre, and of our most illustrious Fellow, William Harvey; for in 1588, the year of the Armada, Harvey was entered at the King's School, the direct scion of the Christchurch Monastery School. There are good grounds for believing that this was the first school to be founded in England. When Augustine and his followers established Christian churches in England, they did not, as modern missionaries do, carry on the services of the Church in the vernacular tongue of the country, but employed the language that had been used in Rome for the last five hundred years. To make themselves understood the Latin missionaries had to come with the Latin service book in one hand and a Latin grammar in the other. Those whom they wished to convert could not profitably go to church till they had first gone to school to learn the language. So the grammar school became the necessary anteroom or vestibule to the church.

Prior Selling was one of the more famous of the priors of Canterbury and was principally responsible for the completion of the great central tower of the cathedral. It was from him that Linacre learnt his first Greek, and it would

have been difficult to find a more appropriate tutor. Much is known and more is conjectured about schoolboy life in Tudor times. Whatever the boys learned or did not learn at school, it is quite clear that they acquired a fair knowledge of Latin. Grammar was regarded as the doorway to all knowledge, and the liberal arts could be approached only through the study of parts of speech—*qui nescit partes in vanum tendit ad artes*. The grammars of Donatus and Priscian usually provided the pathway to knowledge, and they have been described as the schoolmasters of Europe for a thousand years. But Priscian was being superseded by Alexander of Villedieu, the composer of a hexameter poem in 2,645 lines dealing with accidence, syntax, and prosody, the learning of which by heart must have been an intolerable nightmare to schoolboys. So widespread was the use of Donatus that the abbreviation *donet* passed into common use to signify an introductory handbook on any subject, much as we employ the word "primer." Hard as a ten-hour day was to the schoolboy, there were so many saints' days to be observed that hardly a week could have passed without one whole or half holiday. Then, too, in pre-Reformation times there were many peculiar observances. St. John Lateran's day, May 6, was kept by football, a siesta, and an interval for drinking beer, the equivalent of our modern afternoon tea—the ball, the bed, the beer (*Porta Latina pilam, pulvinar, pocula praestant*). Then on St. Nicholas's Day, Dec. 6, there were the boy-bishop celebrations. It is impossible, of course, to draw a picture of the individual boy, but we do know that when Linacre not very many years afterwards was in Italy he was chosen, because of the elegance and modesty of his manners, as the associate in study of Lorenzo de' Medici's children.

It was probably with the assistance of Prior Selling that Linacre in 1480, at the age of 20, went up to Canterbury Hall, Oxford, later incorporated into Christchurch. Here he made friends with Grocyn, a man of 36, and with William Latimer, a youth of his own age. It is not known why Linacre waited till his twentieth year before entering the University, for boys entered much younger than now, and from 14 to 16 was quite a common age. The Warden of New College had introduced Greek lectures there in 1465, and it is presumed that the three friends studied under the guidance of the lecturer, an Italian, Cornelio Vitelli by name. Eventually Grocyn, already a Fellow of New College, was to be the first Englishman to lecture on Greek in Oxford, and later, in London, to share the honour with Linacre of imparting a knowledge of Greek to one of the great figures of history—Desiderius Erasmus. When to Grocyn, Linacre, and Latimer we add the names of the two other friends—Colet, afterwards Dean of St. Paul's and founder of St. Paul's School, and Thomas More, the author of *Utopia*—we have a list of the leading scholars in England devoted to the New Learning and usually known as the English Humanists.

*The Harveian Oration (abridged), delivered before the Royal College of Physicians of London, on Oct. 18, 1947.

A Sojourn in Italy

After four years at Canterbury Hall Linaere was made a Fellow of All Souls. The following year he accompanied Prior Selling, who had been chosen by Henry VII to conduct a mission to the Vatican, to Italy. Linaere appears to have remained in Italy for six years or so, and during this time to have stayed in Bologna, Florence, Rome, and Padua. At Bologna he was introduced by Selling to Politian, the most brilliant Latin poet and scholar of the day, attached to the Platonic Academy, founded in Florence by Cosmo de' Medici. Under the Medici Florence had become the modern Athens, and learning as well as art had found a home there. It is thought that this introduction to Politian stood Linaere in good stead, for when Linaere visited Florence, Politian, whose work it was to direct the studies of the children of Lorenzo the Magnificent, is supposed to have introduced Linaere to the merchant prince. However that may be, Linaere became the recipient of the patronage of Lorenzo, living in the most brilliant court in Europe and sharing the instruction given to the two young princes Piero and Giovanni. The latter ultimately became Pope under the name of Leo X, and in after years was not unmindful of this association with Linaere.

We may be confident that Linaere's association with some of the finest scholars in Italy played no little part in forming that facility of expression, elegance of taste, and accurate skill in the classical languages for which he is famed. It has been said that by Linaere's endeavours Galen speaks better Latin in the translation than he did Greek in the original, and that Aristotle shines not more in his Attic than in his Latin garb. Unfortunately, none of his translations of Aristotle into Latin has survived.

After a year in Florence, then almost at the zenith of her splendour, Linaere made his way to Rome. Here he was befriended by Hermolaus Barbarus, one of Europe's greatest scholars and the translator of Dioscorides' *Materia Medica*. It has been suggested that it was he who may have introduced Linaere to the works of Galen and have influenced him in choosing medicine as his profession. For a charming account of this scholar may I point to the writing of a Fellow of our own College, Sir Henry Bashford, in *The Harley Street Calendar*.

Linaere next visited Venice and, possibly on the commendation of Hermolaus, made the acquaintance of another distinguished scholar. Aldus Manutius Romanus was contributing to the spread of learning by printing the classics in inexpensive octavo volumes—approximately at the price of our Everyman's Library. They were well read, for of the 24,000 copies printed of Erasmus's *Praise of Folly* only one copy has survived, and that is in an imperfect state. Books from the Aldine Press, with their distinctive device of the anchor and the dolphin on the title-page, are much sought after by collectors, distinguished as they are by a high standard of accuracy of text and by beauty of type. The type first used in the Virgil which he published in 1501, known as Aldino or to most of us as "italics," is said to have been modelled on Petrarch's handwriting. Erasmus acted for a short time as his editor and reader. It was for Aldus that Linaere began a translation from the Greek of *Proclus on the Sphere*, said to be the earliest accurate translation of a Greek writer ever made in England, but it does not appear to have been published until twelve years later.

Linaere's next move was to Padua, where he graduated M.D. with great distinction. This we learn from a reference to the event in the *Fructus ex Doctrina*, a book written by Richard Pace, Secretary of State to Henry VIII, and published in Basel in 1517.

His Return to Oxford

Returning to Oxford, which he must have found a trifle secluded after breathing the feverish atmosphere of the Renaissance in Florence and living in the most brilliant court in Europe, he found his friends Grocyn and Latimer awaiting him. They too had made a sojourn in Italy during his absence, and had attended the lectures of Politian and Chalcondylas; but whether they met him there it does not seem possible to determine. No sooner was Linaere back in Oxford than the degree of M.D. was confirmed by an act of incorporation, and it is asserted, without any convincing proof, that by a similar act of incorporation at Cambridge he became an M.D. of that University. The year 1490 seems to be the year in which he graduated in medicine. Caius claims that Linaere resided for a time in Cambridge—a statement which receives some weight from his subsequent foundation of a lectureship in medicine there.

In 1494 Linaere had to mourn the death of his old tutor and kinsman, Selling, who for twenty-two years had been Prior of the Monastery of Christchurch, Canterbury. He is said to have been the first Englishman to visit Northern Italy to study Greek. He died on the anniversary of the death of Thomas à Becket and was interred in the Martyrdom of the Cathedral, the last proof of the respect in which the brethren held the memory of their superior.

In 1499 Desiderius Erasmus arrived at Oxford. Erasmus was an entire stranger in England, brought over by Lord Mountjoy from Paris, and he did not know a word of English. He had come to England in spite of ill-health and poverty to learn Greek. This poor foreign scholar, destined to become one of the great figures of history, whom fortune had used so hardly, cast adrift upon the world without resources—for he had been robbed of his slender patrimony by dishonest guardians—found a friend in Linaere. Writing to an Englishman whose tutor he had been in Paris and who had gone to Italy to learn Greek, Erasmus says:

"Yes, you will say, but how do you like our England? Believe me that nothing in my life has ever pleased me so much. I have found the climate both pleasant and healthy; and I have met with so much kindness and so much learning, not hackneyed and trivial but deep, exact, ancient, Latin and Greek, that I am not hankering so much after Italy except just for the sake of seeing it. When I hear my Coler I seem to be listening to Plato himself. In Grocyn, who does not wonder at that compass of all knowledge? What is more acute, more profound, more keen than the judgment of Linaere? What did Nature ever create milder, sweeter, or happier than the genius of Thomas More? But why should I run through the whole list? It is marvellous how widespread and how abundant is the harvest of ancient learning which is flourishing in this country. All the more reason for your returning to it quickly."

But Erasmus, after conferring such praise, was to receive a rude shock on leaving this island. Henry VII had re-enacted an old law of Edward IV which forbade temporarily the export of gold and silver coin from England. More had assured Erasmus that as long as his money was not in English currency all would be well. Arrived at Dover, Erasmus attested that the money he was taking back had neither been earned nor been received in England, and that he was only taking back what he had brought with him into the country. The custom-house officials were adamant, and of the £20 which he had with him all but six angels (£2) was confiscated. Robbed of his money, he had perforce to stay in France instead of visiting Italy, which had been his intention. It seems very like our own year of grace!

In the year 1501 an event occurred which was to influence profoundly Linaere's future mode of life. Henry VII's

eldest son, the unfortunate Prince Arthur, was sent up to Magdalen, and Linacre was chosen as his tutor and private physician. The prince was delicate and, though only in his fifteenth year, was about to make a diplomatic marriage with a foreign princess—Catherine of Aragon. Linacre must have seen that his charge of the prince foreboded the long the end of his Oxford life and would be likely to entail his definite committal to the practice of medicine. Five months after their marriage Prince Arthur and his wife were struck down by the sweating sickness, which proved fatal to the prince. The princess recovered and later became the first wife of her husband's brother, Henry VIII. Linacre about this time was made domestic physician to Henry VII and, leaving Oxford, moved to London, where he appears to have entered upon the regular practice of his profession. He was certainly the most erudite of those attending the sick in London, but we have no means of assessing his clinical ability apart from the fact that the most distinguished statesmen and courtiers were to be found among his patients—Wolsey, Archbishop Warham, Tunstall (Bishop of London), Foxe (Privy Seal and Bishop of Winchester), and Sir Thomas More. In 1509 he became physician to Henry VIII, and he seems to have found time to direct the studies of Reginald Pole, a future Archbishop of Canterbury, and to help Erasmus with the publication of the New Testament in the original Greek.

John Colet

A short reference must be made to another of Linacre's friends, John Colet, the son of a wealthy Lord Mayor of London, Sir Henry Colet. Colet in 1493 had gone to Paris and thence to Italy to study canon law, patristics, and Greek, and while abroad had become acquainted with the ubiquitous Erasmus. On his return to England three years later he started Oxford in his lectures on St. Paul's Epistles. These were in almost every particular in striking contrast with the dissertations of the day. There was hardly a quotation from the Schoolmen and from the Fathers, but the Epistles were treated as straightforward letters written by a living man to his friends, which invested them with a freshness and an interest quite new to his hearers.

The field of Colet's influence was changed and in some ways widened when in 1505 he became Dean of St. Paul's. Five years later he devoted his patrimony to the foundation of St. Paul's School. Here he decided that the boys, who had to be able to read and write before being allowed to enter the school, should be taught good literature, both Latin and Greek, and that debased mediaeval Latin, "all that abusion that the later blind world brought in and which may rather be called Blotterature than Literature," should be utterly banished and excluded. Colet requested Linacre to write a Latin grammar for the use of the boys. This Linacre undertook to provide, and with great pains and the sacrifice of much time wrote a work consisting of quite a few volumes. As a school book it certainly seems to have been ill-judged, and Colet, finding it little adapted to the requirements of his pupils, put it altogether aside as too long and too learned for his "little beginners." Colet substituted some rudiments of his own composition under the title of *Paul's Accidence* which he dedicated to William Lilly, whom he had appointed as the first High Master. The book was later enlarged by Lilly and by Erasmus and others, and, finally becoming generally adopted in other English schools under the name of *Lilly's Grammar*, it formed the foundation of various Latin grammars used in England up to the middle of the last century. Canon Shirley, Head Master of the King's School, Canterbury, informs me that, though there is no actual record of what Latin grammar was used in the school in the time of Queen

Elizabeth, there is little doubt that Lilly's was the grammar that William Harvey used. Colet's rejection of Linacre's book led to a break in their long-standing friendship, and in spite of the efforts of Erasmus the breach was never healed.

The year 1518 saw the foundation of the College of Physicians, at which time Linacre was 58 years of age. The meetings were held in Linacre's own house—the Stone House, as it was called—in Knightbridge Street, and there they continued to be held for nearly a century. The front portion of the house, consisting of a parlour below and a chamber above to be used as a council room and library, were given to the College during Linacre's lifetime. After his death the remainder of the premises reverted to Merton College, Oxford.

Linacre's Later Years

Two years later Linacre appears to have taken priest's orders, but at the time of the foundation of the College he held the livings of Mersham and Hawkhurst, in Kent, and had been a Prebendary of Wells and a Canon of St. Stephen's Collegiate Church, Westminster. Some have suggested that he had taken deacon's orders in 1505, but it was the practice of the day to present livings to scholars even though they had never been ordained.

Within the last seven years of his life he made and published translations from Greek into Latin of no fewer than eight of Galen's works, the *De Sanitate Tuenda* and the *Methodus Medendi* being published before he retired from practice.

In 1523 Linacre received his last Court appointment, being made, with Ludovicus Vives, Latin tutor to the Princess Mary, then 5 years old, and being charged with the care of her health. He published a simple Latin grammar in English in the same year for the use of his royal pupil. This was afterwards translated into Latin by George Buchanan, the celebrated Scots scholar, who was imprisoned by the Inquisition in Portugal and who during the two years of his imprisonment, 1549–51, wrote a Latin version of the Psalms in various metres.

But perhaps the work that gave Linacre most satisfaction was the *De Emendata Structura Latina Sermonis*. This, which may be called an "Advanced Manual of Latin Prose Composition," had taken many years to prepare and was published in six volumes in 1524, the year of his death. This served to place him in the first rank of Latin scholarship of the day. It was reprinted abroad with a letter from Melancthon recommending its use in the schools of Germany.

During the last few years of his life Linacre, growing more and more infirm, suffered from calculous cystitis, from the effects of which he died on Oct. 12, 1524. Almost his last act was the foundation of three lectureships—two at Oxford and one at Cambridge. The lectures were dedicated to the glory of God and the true art of medicine, and they were to be distinguished by the name of "Linacre's Lectures."

Robert Browning, in his *Grammarian's Funeral*, has given us the picture of an idealist scholar, and it has been suggested that his grammarian was Linacre. I borrow from Sir Henry Bashford:

"With his grammar finished, therefore, and his affairs in order—the house in Knightbridge Street left to the College, and a sufficient income from the rest of his property to provide lectureships at the Universities—he may well have thought in the autumn of 1524, that it was about time for him to be going. In the background of his age he had led a full life; most of its statesmen had been his friends. And if there is just a hint, perhaps, to be found in his will of the Linacre trespass upon by Colet—if he had somehow detected in his

niece Agnes a certain tendency to *laesa majestas*—it was only by the gentlest of posthumous rebukes that she and the world were to discover it. Her sister Margaret, he said, was to have the better of the two beds that he had bequeathed them."

Linaere was buried in old St. Paul's before the rood screen of the west door, a spot chosen by himself. His grave was marked by no memorial for more than 30 years, when John Caius, during his presidency of the College, erected a monument to his memory at his own cost. This perished when the cathedral was destroyed in the Great Fire of 1666.

Caius and Gilbert

John Caius, whose presidency extended with intervals from 1555 to 1571, set out for Italy in 1539 and studied physics at Padua under Montanus, the greatest medical teacher of the time. Caius lodged in the same house as Vesalius, the celebrated anatomist, who possibly may have fired Caius's enthusiasm in this direction, for in 1564 Caius introduced anatomies, as they were called—that is, demonstrations of dissections—into Cambridge. These demonstrations were not the first to be held in England, as they had been introduced 20 years earlier at the Barber-Surgeons' Hall in London, where Caius had lectured on anatomy. He is usually regarded as the founder of the study of anatomy in this country. He is said to have modelled his life upon the example of Linaere, and, like him, devoted much time to the collation and translation of Greek medical writers, but, unlike Linaere, he recorded the results of his own observations. These appeared in 1552 under the title of "A Booke of Counseil against the Disease commonly called the Sweate or Sweating Sickness." This is said to be the first instance of a medical book being published in English, but he afterwards republished it in Latin.

It was Caius who designed the insignia by which the President of the College should be fittingly honoured—the cushion of crimson velvet, edged with gold, placed before the President on all solemn meetings, and the caduceus, its head adorned with the arms of the College supported by four serpents, which the President carries to remind him by its material—silver—as Caius quaintly says, to govern with patience and courtesy, and by its symbols, the serpents, with judgment and wisdom. Caius is said to have foretold the very day of his own death, and to have chosen his own epitaph, *Fui Caius*, still to be seen in the Chapel of Caius College.

Dr. William Gilbert, physician to Queen Elizabeth and James I, and President of the College in 1660, published in that year a remarkable book, *De Magnete*, in which he records his experiments relative to the magnet. Gilbert may therefore be said to have introduced the method of experiment into scientific research. By his will he gave his whole library, globes, mathematical instruments, and a cabinet of minerals to the College, but with the exception of a few folios, which cannot now be identified with certainty, these seem to have perished when the College was burnt down in the Fire of London.

I am indebted to Canon F. J. Shirley, Head Master of the King's School, Canterbury, for copies of the wills of Robert Harvey and of John Harvey—both of Folkestone, William Harvey's birthplace—which I gratefully append.

2. John Edward, John Edwards.

3. John Edward, John Edwards.

"PRC 13, vol. 13 (Act book), f. 45.

"23 Feb. (1552-3). Admin. of goods of John Harvie of Folkiston' intestate; admin. to Florence widow, sworn, &c. Bound with her Thos. Baker, Jurate of Folkestone, & Hy. Hogben of same yeoman in £40.

"(It is slightly ambiguous as Baker is called *jurat.*=either sworn or jurate. I think it means he is Jurate of the Town of F.)"

In surveying this progress we become conscious of the various phases through which medical endeavour has passed. Contemporary medical practice and knowledge in Linaere's time was a confused mixture of empiricism, folklore, astrology, and magic. Such vestiges of Greek medicine as remained were often tainted, for they had come through the medium of Arabian and Syriac translations from the original Greek texts, and these in turn had been translated again into Latin and contained many inaccuracies. Hermolaus Barbarus, for instance, is reputed to have restored no fewer than two thousand passages in the works of Pliny. Linaere by his careful and accurate translations from the Greek into Latin was able to bring to the notice of his contemporaries the conclusions of Hippocrates, Aristotle, and Galen, based as they were on the simple yet valid foundation of direct observation. By the very nature of things, and to clear the stage, so to speak, he was obliged to look backwards. Caius advanced a step further. In common with Linaere he was strongly attracted to the writings of Galen, and when in Italy had spent much of his time carefully collating the manuscripts of that author, but to scholarship he added the practice of direct observation. This is seen in his devotion to practical anatomy and in his clinical observations set out in his book on the sweating sickness. Gilbert advanced further still: not content with observation, he introduced the method of experiment into scientific research. As Sir Walter Langdon-Brown has aptly said, "Linaere looked to the past for the Revival of Learning, Caius faced both ways, but Gilbert steadfastly looked forward."

THE LOCALIZATION OF DEEP PAIN

BY

J. B. HARMAN, M.D., F.R.C.P.

Physician to Out-patients, St. Thomas's Hospital

This paper is concerned with the laws that determine where a deep pain is felt or, in other words, with its local sign. It is intended to show that the pain is not felt in any particular structure of the body, such as viscera or body wall, but that it is best regarded as a projection from the brain—to show in effect that the place where a pain is felt is determined as much or more by the anatomy of the cortex as by the structure of the limb or part of the body in which it seems to be. The view has indeed been hinted at from time to time, and has received a more definite statement from Lewis (1942). I believe it to be in harmony with current ideas on perception and to provide an explanation for those vexatious experiments with "novocain" block and phantom limbs.

It will not be necessary to review the many theories of the last fifty years, but since our common beliefs are still coloured by the traces they have left behind them it will be better to clear the ground by stating three propositions that may be regarded as proved. The first is that viscera can in fact be pain-sensitive. As is well known, Lennander (1902) popularized the view that they were insensitive, and this was widely held until Hurst (1911) showed that distension could cause pain in the oesophagus and rectum. Since then many other instances have been recorded in which

pain originated from a viscus, and it is now generally agreed that viscera may be sensitive provided a suitable stimulus is used.

The second proposition is that pains from viscera and deep structures are essentially the same. The suggestion that visceral pains were different from others rested on certain interpretations that have now lost their force. In any case the distinction became meaningless when it was shown (Lewis, 1938; Lewis and Kellgren, 1939) that phenomena which were supposed to be characteristic of visceral pain—such as dull quality, tendency to spread segmentally, associated muscular rigidity, and so on—could be produced equally well by injuring deep somatic structures. Lewis (1942) concluded that the proper distinction is between pains that come from deep structures, like viscera and ligaments, and those that come from the superficial parts, such as skin.

The third proposition is that there is only one kind of deep pain and that it is not divisible into local and referred. These two kinds were postulated to account for the fact that, whereas it could be said that stomach pains coincided with the stomach, it was obvious that angina and renal colic were felt a long way from their site of origin. Again, it was Lewis (1942) who argued that the distinction was unnecessary, for he believed that deep pain always had a spreading segmental distribution. The apparent anomaly is merely due to the anatomical accident that the heart is part of a segment that stretches down the arm, whereas the stomach and the rest of its segment are in roughly the same position.

Pain "In" and "From" a Viscus

The equivocal meaning of language has caused a confusion of thought that must be cleared up before the real problem can be seen. It has, for instance, been tacitly assumed that having a "pain in a viscus" expresses the same notion as having a "pain in a finger." Much experimental ingenuity has been expended on trying to decide whether it is possible to feel a pain in a viscus, yet no conclusions have been or, indeed, can be reached. The problem is not physiological and soluble by experiment, but philosophical and linguistic, and can be settled only by examining the meaning of words. Thus, if a man says he has a pain in his finger, the ordinary English usage is accepted and everyone knows what he means. We all know we have a finger, and we know where it is and we have felt pain in it. But a man could not say with the same meaning, "I have a pain in my Meckel's diverticulum" even if it should indeed be producing colic. For of all those who have suffered this pain there must be few who have ever heard of the organ, fewer still who know they have one, none who could know where it was lying, and all would have felt a pain that was "bigger" than the organ it was supposed to be in. Anyone who makes such a statement is not talking of his perceptions, but is making a diagnosis, assailable by evidence and argument. And he may be proved wrong. But if he said he had a pain in his belly his statement would be accepted, for it is a matter of common experience that men perceive their bellies and that most have had pains in them.

It is therefore important to bear in mind the distinction which is so often overlooked between pains that come from a part and pains that are felt in it. We believe it to be meaningless to say that a man feels a pain in an organ that he cannot perceive, and the implication that an anatomist could feel pains where the layman cannot is absurd. So we must reject any theory of deep pain that admits of its being felt at the site of origin. The problem can then be stated thus: "Where is a deep pain felt that comes from an unperceived structure?" It occurred to me that the

answer might be had from persons with phantom limbs, for they have the perception of a part, yet are unencumbered by its real presence.

Referred Pains in Phantom Limbs

In subjects who had had an arm amputated a deep pain was produced by injecting 6% saline into the interspinous ligaments. The sensations of the normal arm were compared with those of the phantom.

Case 1.—J. J. H., aged 50, had a road accident in 1929 which caused loss of all power and sensation in the right arm. One year later it was amputated at the shoulder. Examined 1940. The phantom remained unchanged all these years. It is immovable and in the position in which his arm was slung before amputation. The arm and forearm appear to be half as long as normal but the hand twice as big. The whole phantom is quite clear. The hand feels as if it is being squeezed, the rest just dull and heavy. The effects of an interspinous injection were:—*Normal arm:* Stabbing and tingling sensation in middle finger and ring-finger when the needle was introduced, becoming more severe with saline. *Phantom:* Tingling in middle finger and ring-finger; the wrist feels as if it is being tightly squeezed, the elbow very slightly so.

Case 2.—F. C. Y., aged 59, had a gunshot wound of the left arm, forearm, and elbow in 1916. Amputation above the elbow was done three months later. Examined 1940. The phantom remained unchanged. It consists of hand and wrist only, placed about 12 in. (30 cm.) higher than normally. The thumb and forefinger are most distinct, the whole part being numb. There is possibly some movement. The effects of an interspinous injection were:—*Normal arm:* Sharp tingling pain in hand and elbow. No aching. "I know something is going on in it." *Phantom:* Similar sensations, but stronger, "like electricity"; distribution is in the inner and outer border of the hand and in the whole forearm, which appeared for the first time; no aching. An injection into the erector spinae muscles was given. It produced severe aching along the inner side of the stump—"rheumaticy pain like a bag of nerves"—after a few seconds a numb sensation was felt in the inner and outer border of the phantom hand, different from that in the stump and "more like the return of sensation after a very severe accident."

Case 3.—C. F. M., aged 55, had all the tendons of the right hand cut by a shell splinter during the 1914-18 war. A below-elbow amputation was performed the same night. An immediate phantom was just like a real hand. In 1932 he had a stroke and could not speak for four months. Examined 1940. The right leg and stump were still spastic, the movements of phantom thumb remaining unimpaired. Phantom now smaller than normal and nearer to stump. Injection into erector spinae at base of neck resulted as follows:—*Phantom:* Dull rheumaticy pain inside stump at the back of the forearm. Passed into phantom in the back of the knuckles and fingers as a pricking and tingling sensation, quite different from the ache in his stump.

Case 4.—G. M., aged 33, received a gunshot wound at Anzio, with immediate guillotine amputation above the elbow as P.O.W. Clear, complete phantom, still bleeding and itching; he has tried to use it on several occasions. Two months later reamputation was carried out to the shoulder. Examined in 1946. He has three shooting pains at the level of the elbow as if they were in fingers, but no fingers are felt: this appears to be the remains of his first phantom. He also has a dull aching phantom of his first amputation stump. An interspinous injection had the following effect:—*Phantom:* Gripping sensation in the elbow-joint as if something had been tied tightly round it, and there was a cramp. "I often get that feeling if I have a blow on the shoulder—it is very slight." The sensation can be imitated by squeezing the normal arm fairly firmly with the whole hand.

It will be seen that pain does spread down into the phantom, where it sometimes has the normal dull gripping quality of roughly segmental distribution. But at other times it was numb and tingling, and might not be strictly

segmental, being felt only in the elbow or wrist. These are differences from the classical deep pain, but they are not thought to be due to the conditions of the experiment, because such variations may be described by patients with normal angina. Since these experiments were undertaken, Cohen and Jones (1943) have published two remarkable cases with angina pectoris in phantom arms; the arm pain was abolished when the brachial plexus was blocked with procaine. I myself have recently seen another such patient.

Case 5.—A.C., aged 66, had a gunshot wound in 1915 through the upper left arm, which was amputated the next day. The phantom used to be a hand and elbow at a normal distance from the shoulder. The arm has now got shorter and the elbow is represented only by an occasional pain. The hand is clenched and can be opened slightly. It feels "kind of numb and is always warm." Eighteen months ago he became subject to a pain in his chest. It starts in the centre of his sternum, "like a very bad wind pain, turning over and gripping my chest." After a time it works down the arm and is like pins-and-needles in the hand. At first it came on at night in bad attacks once a month or so. It used to wake him up, and he had to stand by his bed. Now it comes on when he walks, always after a certain distance. It goes in a few minutes if he rests. He is a diabetic of ten years' standing. Arteries of limbs and optic disks normal for age. Radioecopy showed the left ventricle slightly enlarged; E.C.G. normal.

These observations prove that it is not necessary for the sufferer to possess the part in which pain is felt. It appears to be sufficient if he feels as though he has it. Now it may be that this phenomenon is merely a sensory perversion of a mutilated body. But it is hardly likely that a phantom bears no relation to normal perception of the body or that it has a special pain mechanism of its own. It will therefore be worth while to consider the hypothesis that deep pains in the intact man are also localized as it were in a phantom that corresponds with his real body. In other words, the solution of deep-pain localization will not be sought in possible changes in the peripheral body where it is felt, or the nerve tracts connected with it, but in the mechanism of body perception, which is a function of the cerebral cortex.

Phantoms and the Body Image

Head and Holmes (1911) used the term "body image" to describe the conception that a person has of his own body—of its size, shape, surface, depth, and movements—by means of which he is able to move parts of the body in relation to the whole, and the whole in relation to the environment. The body image is built up by the higher levels of the sensorium from peripheral sensations. It grows throughout life as these sensations are integrated, and it changes slowly as the real body alters its shape.

In the ordinary course of life the parts of the body are so often found where they are expected to be that it seems that their image and reality necessarily correspond. But there are occasions when they do not. Thus certain hemiplegics may feel as if their arm is stretched above their head, whereas it can be seen lying by their side (van Bogaert, 1934). They have a real arm and a phantom arm separated from it. The amputee loses his real arm, but its image persists. The neuroma continues to transmit impulses that are interpreted, on the basis of previous experience, as "an arm." Parts such as the fingers and joints, of which a person is normally more conscious, tend to persist in the phantom, while the upper arm may be represented merely as a distance that the elbow is from the shoulder. When a phantom goes it disappears piecemeal, the clearer parts remaining till the last, so that in the end it may be a thing more than fingers growing from a stump (Head, 1911). Conversely, cortico-thalamic lesions may cause an *armelia* (Nishien, 1935) in which the image of

the right side of the body is lost but the part remains. The patient does not merely lose sensations from that side; he ceases to perceive it, and if he is shown his arm he cannot conceive that it is his. This amputation of the body image may be so severe that the patient cannot even imagine a right side either to his own body or to the world around him.

If a part is anaesthetized we find a disturbance of the relationship between the body and its image which is peculiar. A patient certainly feels the presence of a blocked arm, for he does not become incapable of conceiving such a thing as he would with agnososomia, nor is he just unaware of it as he is of his pancreas, yet it feels different to him both from a normal arm and from a phantom. An anaesthetized part is usually described as being dead or heavy, so that an arm hangs like an artificial limb from the sentient shoulder and the jaw feels like a swollen prosthesis. In fact, in some respects they cease to feel like parts of the body. This raises the question of how one distinguishes one's body from the environment—an important distinction in this connexion because it is the general experience that pain is felt only in the body and not in surrounding objects. It seems that the boundary is drawn between the body that has, or appears to have, innate sensibility and the environment, which, however much sensation may be projected into it, does not itself "feel." On the one hand we have the trunk, limbs, and phantoms; on the other, hair, clothes, and tools, which are perceived to be distinct, though, as Head and Holmes (1911) remarked, they may be incorporated into the body image. In this latter class we put also real parts of the body, such as colostomies, prolapses, and anaesthetized members, which are equivalent to the environment because they cannot feel, but are carried round with the same care and sense of ownership as a hat or stick.

Deep Pain and the Body Image

In the normal man deep pains are felt inside the body. This is consistent with the body image's property of having depth as well as surface. Although the pains are felt deeply they are confined to regions nearer one surface than another. There is a strong tendency for these regions to be in the front of the body even when the stimulus is near the back, but there is less tendency for a pain arising near the front to be referred backwards; in fact, a pain arising more or less centrally is usually referred to the back only after it has reached a certain intensity in the front. There is also a tendency for trunk pains to be referred down the limbs, and pains within the limbs to be more pronounced in the joints than in the length between. On the other hand, deep pains arising within the limbs spread back beyond their origin only if they are severe. This distribution corresponds with the more vivid parts of the body image, for the individual has a clearer consciousness of the front of his body than the back, of his limbs than his trunk, and, as phantoms show, of the joints than the segments between. An unsophisticated housewife was asked why she thought her angina was worse in her elbow than in her arm. She replied, "I suppose it is because you feel your elbow more, don't you think?"

Organic pains are sometimes distributed in an unusual way, referred to scars, or felt more intensely over significant parts such as the heart or appendix. There are also indications that pain may be diverted from its usual site to some other part that has been rendered habitually painful by another stimulus, such as gall-bladder pains that are referred to the left arm in subjects prone to angina (Jones, 1943). Those who have written much on the subject of deep pain (Head, 1894; Maekenzie, 1918; Lewis, 1942) have been forced, after expounding their views, to point out that their

are always cases of bizarre distribution which cannot be explained. It must indeed have been the experience of most physicians that patients will on occasion persist in describing pain references which do not correspond with any known mechanism. Possibly some of these will be found to depend on unsuspected peripheral lesions. But others may well be determined by some higher cerebral organization, and this may be found in variations of the body image. Such variations exist; for some people, for example, have an accurate conception of their body and are skilful in its use, while others are clumsy and uncontrolled. Further, vividness of parts may be enhanced by past events or peculiarities of temperament—the amputation phantom remains crushed and bleeding as the real part was—and studies of normal and abnormal psychology indicate the differing values that men may give to parts of their bodies. Since the body image itself can vary, some variation in pain reference would be expected.

The interpretation of procaine-block experiments in these terms is that pains are not projected to anaesthetized parts, because they are in effect equivalent to the environment. Pains are always felt in what appears to the sufferer to be his own body, and even if he only knows he has a pain "somewhere" it is never somewhere outside himself. Those, however, who have tried to abolish deep pains by local analgesia have had conflicting results (Lemaire, 1926; Weiss and Davis, 1928; Rudolf and Smith, 1930; Morley, 1931; Woollard, Roberts, and Carmichael, 1932). No doubt this is partly due to the difficulty of experimenting with deep pain and to confusing it with reflex hyperaesthesia, but the unjustifiable assumption has usually been in the mind of the experimenter that the pain must be either "in the viscus" or "in the body wall." A straight answer cannot be given to a question that ignores the possibility of its being in neither. The discordant results can, however, be reconciled by the present hypothesis, for how much of a pain can be abolished will depend on how much of it is projected into the interior or surface of the body image, and on how completely these parts can be anaesthetized. It is, for example, relatively easy to abolish an anginal pain that is deep in the arm by blocking the brachial plexus. The pain that is felt near the surface of the chest can be banished or modified by anaesthetizing these parts. It may reappear in a neighbouring area, to be chased to yet another when that is blocked in its turn (Jones, 1943). This is an artificial alloaesthesia in which pain is diverted to the new site, or is noticed for the first time in it, after the most favoured part of the body image has been destroyed by anaesthesia. On the other hand, the pain that is felt deep in the chest always remains in these experiments, however many anaesthetic patches are produced on the surface. This has been interpreted as the true local pain felt in the viscus. But it is better regarded as pain persisting in the interior of the body image. The internal pain remains because the spatial perception of the chest into which it is projected is unaffected by such procaine block as is practicable. Indeed, perception of the anterior could not be abolished without anaesthetizing so much that the visceral afferents themselves would be interrupted at the same time.

The argument that deep pain spreads because it cannot be localized to the unknown region where it arises needs some elaboration, for there are parts of the body that are very accurately perceived yet give deep pain. For example, the finger-joints are particularly vivid in the body image, and we are certainly aware of the position and movement of muscle masses or imbedded bones, but all of them give poorly localized deep pain. In other words, why does not pain from these parts have a local sign that approaches the accuracy of that in the skin? This question cannot of course be properly answered without understanding the

mechanism of local sign in the skin itself, but it may be observed that there are various modes of perception which are not all equally important in giving local sign. Sensations such as touch are concerned with the body surface only, of which they give a very detailed map; while proprioceptive sensations are the basis of perception of body space, position, and movement. Perception of a finger-joint is a combination of both, built up from perception of its surface and knowledge of the space it encloses. But our knowledge of this space is limited to its shape and dimensions, and the map of the interior is as blank as that of the trunk. Stimuli in both are in *terra incognita*, and the pain that results has the same characteristics. Inevitably a deep pain in a finger must, if it is to remain in the body, be confined to a smaller space than a pain in the abdomen, and for this reason will give the impression of being more accurately localized. But this is a false impression, as can be seen by considering angina. The pain that spreads to the finger seems to be more accurately placed in the body than the pain in the chest, but this is not an accuracy of local sign, for the pain is felt a whole arm's length from where it arose.

Deep Pain and the Segment

In discussing the body image we have been exclusively concerned with the higher analysis of deep pain. But the region in which pain is felt must be determined to a large extent by the fixed structure of the nervous system, for otherwise all pains from unperceived organs would be felt together in the most vivid part of the body image—in the face or hand, for example. It has been recognized for fifty years (Ross, 1888) that this region was the spinal segment, and we have to inquire how it is that the sensation of pain caused by a cardiac infarct, for example, becomes segmental and spreads to the arm. This radiation was originally supposed to occur in the cord, because this is where the sensory nerves from the whole segment are first grouped together. Although there is some interconnexion here, as reflex rigidity and hyperaesthesia show, it is difficult to imagine any possible mechanism at this level, and certainly none has been demonstrated (Lewis, 1942). Even in the last century (Sherrington, 1898) it was shown that local sign of superficial sensations must be a function of the brain, for it certainly was not an inherent quality of any sensory nerve. Thus burning a finger sets up impulses characteristic of pain alone, and not of "pain from a finger." The assigning of a place to the crude sensation depends on the integration of other sensory impulses and on the fixed structure of the sensorium where it occurs. If the same holds good for deep pain one would expect to find some evidence of segmental anatomy in the cortex to account for this type of spread. Such is the case, for recent work with fine methods of cortical analysis proves that "the body surface is projected dermatome by dermatome upon the post-central gyrus. The serial order is that of the dorsal nerve roots except that the cervical segments appear in the reverse order" (Fulton, 1943). Most of the work has been done on primates and has been concerned with superficial sensation and movement, but there is every reason to believe that the general style of cortical architecture is the same in man, and that it applies to deep pain also. The segmental spread of deep pain may then be regarded as nothing but a sign of activity at a certain level of the nervous system. We can say what that level is from the symptoms, just as we can diagnose the site of a lesion from the type of palsy or fit it produces. The segmental disturbance does not occur at the highest sensory level, for the segment does not exist in the body image—no man perceives his segments in the way that he is aware of his hand or mouth. So perhaps it is not surprising that pains are rarely

left filling such a meaningless territory as this, but are modified in the way that has been noted until they correspond with the body as the sufferer perceives it.

Summary

Deep pain, unlike superficial sensation, comes from parts of the body that are unperceived and to which, it is argued, no sensation can be localized. All sensations are normally felt somewhere, and deep pain must therefore be an alloaesthesia. It is suggested that these "pains from nowhere" are projected into the perceived parts of the body. They have a segmental basis derived from the fixed structures of the cortex. Their locality is further defined within these crude limits according to the individual characteristics of the body image. The sensation of deep pain does not depend on any peripheral change in the part where it is felt. But its location does depend on the normal stimuli coming from the part, for without these the place would remain unperceived.

THE PRE-ERYTHROCYTIC STAGE OF MAMMALIAN MALARIA

BY

H. E. SHORTT, M.D., D.Sc., D.T.M.&H.

Director, Department of Parasitology, London School of Hygiene and Tropical Medicine

P. C. C. GARNHAM, M.D., D.P.H.

Reader in Medical Parasitology, University of London

AND

B. MALAMOS, M.D., D.T.M.

Lecturer, University of Athens

Since the discovery of the part played by the mosquito in the transmission of malaria there has remained a gap in our knowledge of the cycle of events. This has been our complete ignorance of what happens to the sporozoites injected by the mosquito during the period between its bite and the appearance of erythrocytic parasites in the circulating blood. Schaudinn's (1902) observation of the sporozoite entering a red cell has never been repeated and has long been suspect, and the most generally held theory of recent years has been that some form of development takes place in the internal organs—probably in the reticulo-endothelial system—before the parasites enter the red cells and circulate at the end of the incubation period. This interval has been considered to be a period of about

The curtain was first really lifted in the case of avian malaria when James and Tate (1937) described the erythrocytic cycle in *Plasmodium gallinaceum*, but the developments following the introduction of sporozoites by the mosquito remained a mystery. The next step was the discovery by Mudrow (1940) and Shortt, Menon, and Iyer (1940) of developmental forms of *P. gallinaceum* in the incubation period; these were schizogony forms reticulo-endothelial cells. Reichenow and Mudrow (1940) next gave a detailed description of the forms found during the incubation period in infections with *P. relictum*, and Huff and Coulston (1944) independently described in even greater detail the course of events in *P. gallinaceum*.

All this work led to the belief that some parallel development must take place in the case of mammalian (including human) malaria, but all attempts to demonstrate this proved unsuccessful. Efforts to discover the incubation period stage of mammalian malaria—i.e., the hypothetical pre-erythrocytic stage—were given a stimulus by the work of Fairley (1945) at Cairns, Australia, during the recent world war. Fairley and his co-workers showed that during the biting act of the malaria-infected mosquito, and for about half an hour afterwards, blood inoculated from the bitten person into a volunteer produced an infection. After this period and until the appearance of the parasites in the circulating blood even large quantities of blood from the volunteer produced no infection in another individual.

From these results and others obtained in the field of chemotherapy—for example, Davey (1946)—it was evident that shortly after the introduction of sporozoites they disappear from the circulation and the further development during the incubation period takes place in some protected site outside the general circulation.

Hitherto there has been little to support this hypothesis in the form of actual findings in mammalian malaria. Raffaele (1937) described bodies found in smears of human bone marrow and considered by him to represent stages in the development of sporozoites. Somewhat similar observations have been made by other workers in this field up to the present date, but none of these have been confirmed or have even received much support.

Large-scale experiments with *P. cynomolgi* carried out by the Mammalian Malaria Inquiry under the Director, Central Research Institute, Kasauli (1946), and similar investigations by Huff and Coulston (1947), have yielded negative results.

In the Department of Parasitology at the London School of Hygiene and Tropical Medicine investigations to discover the pre-erythrocytic stage of *P. cynomolgi* in the rhesus monkey have been in progress since 1945, and the most recent experiments have at last resulted in the discovery of this stage, as briefly reported by Shortt and Garnham (1948).

Description of Experiment

We do not propose to give the details of all our work, but will confine ourselves to a description of our most recent successful experiment. More than 1,000 *Anopheles maculipennis atroparvus* bred in the laboratory were fed on a monkey showing mature gametocytes in the peripheral blood. The mosquitoes were subsequently fed on another infected monkey and were given a third feed on the original animal. The interval between the first and third feeds was eleven days. The mosquitoes were maintained at 26° C in a relative humidity of approximately 80%.

Ten days after the last infective feed 20 mosquitoes were dissected and without exception proved infected, most of them with extremely numerous sporozoites in the glands.

survivors, 576 in number, were given the feed upon a clean rhesus monkey; over 500 re batch of mosquitoes was then ground up ml. of heparinized monkey plasma diluted solution. Half the suspension was inoculated into the same monkey and the other muscles of both sides. The suspension

showed an average of 5 sporozoites per field of the 1/12 oil-immersion objective.

The monkey was sacrificed seven days later and a very complete necropsy was conducted.

The tissues given in the list which follows were taken for examination either in smears or in sections, or both: Spleen, liver, kidney, suprarenal gland, pancreas, small

FIG. 1.—Section of liver showing schizont of *P. cynomolgi*, containing well-marked vacuole. Mod. Giemsa stain ($\times 500$).

FIG. 2.—Section of liver showing schizont of *P. cynomolgi*, with numerous masses of chromatin. Mod. Giemsa stain ($\times 1,000$).

FIG. 4.—Schizont of *P. cynomolgi* found in an "impression smear" of liver. Giemsa stain ($\times 1,000$).

intestine, lymph glands from various parts of the abdomen, aorta, inferior vena cava, peritoneal exudate, peritoneum, lungs, heart, thoracic glands, bone marrow, brain, leg muscles, stretch preparations of pia mater and omentum.

The fixatives used were Zenker, Carnoy, Flemming, and 10% formol-saline. Suspensions in citrated saline of the following tissues, in the amounts stated, were inoculated into clean monkeys both intraperitoneally and intramuscularly in each case: liver, 10 ml.; spleen, 8 ml.; brain, 7 ml.; lung, 12 ml.; kidney, 8 ml.; peritoneal fluid, 4 ml.; and heart blood, 7 ml. All the monkeys have remained negative for a month.

The slides of material were stained with haematoxylin and eosin or Giemsa, using the modification of McNamara's stain described by Shortt and Cooper (in the press). The latter unquestionably gives the most brilliant results, and the description given below applies to parasites stained by that method.

Pre-erythrocytic Stage on Seventh Day of Incubation Period

Up to the time of writing we have not had the opportunity of examining thoroughly all the tissues taken, but a rapid survey has resulted in the finding of parasites in the liver only. In a section of the liver examined with the 2/3 objective, small areas of blue colour and ovoid shape are seen very thinly scattered throughout the section (Fig. 1). In one typical section with an area of 90 sq. mm. there were 36 such areas. The ovoid shape is not invariable, and some parasites may show minor indentations, whilst in a few cases actual blunt pseudopodiarms exist. The parasites measured an average of 26μ in the longest diameter, but larger forms up to 30μ or more occur.

When examined under high power these blue areas are seen to be plasmodial masses undergoing schizogony (Figs. 2 and 3). The cytoplasm stains a cobalt blue and has an opaque semi-reticulated appearance, while the particles of chromatin stain a magenta colour. In the majority of the parasites there is no evident condensation of cytoplasm around the chromatin masses, but in a few cases in sections cut at 2μ thickness there is a distinct indication of this process which would result in the formation of merozoites. We have seen parasites in the circulating blood on the ninth day after infection; it is therefore evident that merozoite production must have taken place about the eighth day and the forms described above would be the first stages in the process. For the same reason we conclude that the majority of the forms in the liver are nearly mature and at the stage immediately preceding merozoite formation.

In a considerable number of schizonts there appear one, two, or even multiple vacuoles (Fig. 1) with sharply cut outlines. These tend to be smaller the more numerous they are. It should be mentioned that at no stage is any pigment to be seen in the parasite.

It is very difficult to be certain of the number of particles of chromatin present, especially if the counting is performed on serial sections, because parts of the same fragment may be counted twice, and for this reason we have based our estimate on schizonts seen in an impression smear (Fig. 4). The number was estimated to be between 20 and 30 in a single schizont.

As regards the relationship of the parasite to the liver tissue we do not at present feel inclined to be dogmatic, and a final opinion can be formed only when younger stages of the parasite have been examined. The general impression, gained by us, however, is that the parasites are contained in the parenchyma cells, and this

opinion is strengthened by the appearance in sections stained by Gömöri's stain to show the reticular fibres. In a monkey sacrificed on the sixth day the parasites in the liver exhibited few, if any, differences from the seventh day forms.

Discussion

The importance of this discovery lies in the fact that the resemblance of *P. cynomolgi* to *P. vivax* of human malaria is so close that the findings here described will almost certainly be applicable to the human parasite and, therefore, that the liver is the most likely site for the human pre-erythrocytic forms.

Until we have seen the earlier pre-erythrocytic stages of *P. cynomolgi* we feel that we are hardly in a position to discuss the relationship of the forms found by us to comparable stages of other pigment-producing blood parasites. On the other hand it may be noted that there is a superficial resemblance between the liver schizonts of *P. cynomolgi* and the tissue phase of *P. gallinaceum*, where, however, the merozoites would appear to be more numerous. There is an even closer resemblance to the early exo-erythrocytic stage of *Hepaticocystes (Plasmodium) kochi* (Garnham, in press), although it must be remembered that the fully developed stage of the latter in the liver measures 2 mm. in diameter—i.e., at least 80 times the size of the mature *P. cynomolgi* schizont.

The failure hitherto to find pre-erythrocytic stages of mammalian malaria may be attributed to certain factors: (a) the dilution factor, which necessitates an enormous dosage of sporozoites if the developmental forms are to be readily found; (b) examination of smears has been more intensive than of sections; in smears the parasites are less readily found. The fact that exo-erythrocytic forms had not been found in mammalian malaria may be due to their possibly evanescent nature. It seems likely that the majority, at least, disappear with the establishment of the erythrocytic cycle.

We wish to acknowledge the great help we received in this investigation from our laboratory staff. Mr. W. Cooper with his great technical skill and experience has been invaluable and was ably seconded by Mr. E. Blackie, while Miss J. Stedman gave valuable assistance in mosquito technique. We are also indebted to Mr. W. Alves, B.A., for assistance in the critical necropsy on the first monkey in which we found pre-erythrocytic forms.

Nurses, medical auxiliaries, and certain other hospital or allied workers are excepted from the Control of Engagement Order, 1947. Hospitals and employing authorities may therefore advertise for and engage such staff without reference to the Ministry of Labour and National Service. Those excepted include the following: State-registered nurses, student nurses, health visitors, midwives, and certain unqualified persons on nursing duties, such as nursing auxiliaries. Domestic workers in hospitals are covered by the Order, under which hospital domestic work is regarded as essential work. Full details are contained in the Ministry of Health circular 1/48, dated Jan. 15.

THE ROLE OF TRICHLOROETHYLENE IN GENERAL ANAESTHESIA

BY

GORDON OSTLERE, M.B., B.Chir., D.A.

Senior Resident Anaesthetist, Hill End Hospital
(St. Bartholomew's)

Although it is well over five years since trichlorethylene was first introduced as an important anaesthetic (Hewer, 1942), it still remains as much a suspected and misused drug in some quarters as it is appreciated as a useful agent in others. Although the object of this paper is briefly to review and estimate the position of this anaesthetic in present-day practice, there is little that can be added to the excellent article by Enderby (1944) on the use and abuse of trichlorethylene. It is not intended here to touch on the most important function of trichlorethylene as an analgesic.

Safety

No one can disagree that safety is the first consideration with regard to any anaesthetic. Trichlorethylene (as trilene[®]) has been employed at Hill End Hospital since January, 1940. During this time it has been used on over 10,000 occasions, of which about a third were for induction and about two-thirds for both induction and maintenance of anaesthesia. The drug was administered in most cases by means of the Boyle semi-closed apparatus. We have never experienced any fatalities or incidents of collapse that could even remotely implicate trichlorethylene. Cases reported as primary cardiac failure have come from Haworth and Duff (1943), but it is difficult to be definite that this condition was the cause of the deaths. A more recent case that has been brought to our notice is even less conclusive. Trichlorethylene has now been employed so extensively that if at all shared the dangers of chloroform, as some anaesthetists believe, several unequivocal cases would surely have come to light.

Toxic Effects

Cardiac.—Arrhythmias as described by Enderby (1944) occur in about 5% of cases. They do not arise in any particular type of case or operation, and their cause is obvious in neither the patient nor the administration. The occurrence of arrhythmias under trichlorethylene anaesthesia, as with cyclopropane, has not shown itself as a dangerous condition in the cases in our experience. These arrhythmias, however, indeed, never produced any untoward effect on the patients, and we have never been deterred from making use of trichlorethylene for all cases, save those with a pre-established arrhythmia or history thereof. We have often employed the drug for thyrotoxic patients presenting no history of auricular fibrillation, and have found no abnormal effect on the cardiac rhythm. Most arrhythmias are transient, especially if occurring early in the administration, and call for nothing more than the assurance of an adequate oxygen supply to the patient. Should the disorder persist the trichlorethylene is discontinued, with the substitution of ether if necessary.

Respiratory.—Tachypnoea is very common, and can be produced to some degree in almost every case anaesthetized with trichlorethylene. The increase in the respiratory rate is caused by the action of the drug on the pulmonary stretch receptors (Whitteridge and Bülbüfing, 1946), which accounts for both the rapidity with which the condition occurs and the speed with which it can be abolished by withdrawal of the drug. The only means of combating an established tachypnoea is the abandonment of the administration of trichlorethylene. If the maintenance is continued solely by

gas and oxygen it will often be found that the anaesthesia remains satisfactory. This is no doubt due to the low volatility of trichlorethylene and its consequent low rate of excretion—two factors that can be turned from a potential disadvantage to a real advantage, in that the drug may in all cases be discontinued early in the administration, the amount already given maintaining the anaesthesia. Tachypnoea can be avoided by so administering the anaesthetic that not more than a trace of trichlorethylene—1 dr. (3.5 ml.) an hour—need be given for any length of time. A narcosis must first be established by means of thiopentone, ether, or any other suitable agent, after which trichlorethylene can be employed with a 20% mixture of oxygen in gas for maintenance. There is no doubt that the secret of a successful trichlorethylene administration lies in the employment of only small quantities of the drug.

Metabolic.—Acetonuria occurs quite often after trichlorethylene (Hewer, 1943), as with all local and general anaesthetics (Schulze, 1924). The toxic effect of the drug on the liver has recently been investigated by means of the cephalin-cholesterol flocculation test (Armstrong, 1947) and found to be both transient and less than that of ether.

Bleeding.—Complaints have been voiced by some surgeons that trichlorethylene causes more bleeding than ether. We consider that these complaints, which are not uncommon when either a new anaesthetic or a new anaesthetic is introduced, are unfounded except when a pronounced tachypnoea is occurring.

Palsies.—Three to four years ago reports of cranial-nerve palsies following trichlorethylene anaesthesia appeared in the literature. Hewer (1943) reports three cases that were obviously due to gross contamination of the anaesthetic liquid. Humphrey and McClelland (1944) report 13 cases, of which two were anaesthetized with trichlorethylene in the closed-circuit apparatus, the remainder receiving cyclopropane or ether from the same apparatus. They consider the lesions were probably due to the toxic effect of dichloroacetylene formed from trichlorethylene in the soda-lime canister. McAuley (1943) reports three cases of bilateral trigeminal anaesthesia following the administration of trichlorethylene on the closed-circuit system. The case reported by Enderby (1944) also received the drug by means of this type of apparatus; while Carden (1944) reports two cases—one of which was anaesthetized with trichlorethylene in the closed system, the other receiving cyclopropane by means of a similar apparatus immediately after a trichlorethylene anaesthetic had been given. Carden points out the great importance of the composition of the soda-lime. The unfortunate sequelae occurred after the employment of a brand of soda-lime that contained nine times as much sodium hydroxide as the usual preparation, as well as proving itself more hygroscopic and generating more heat when in use. It would perhaps be fairer to lay the blame for these nerve lesions on the soda-lime than on the anaesthetic. We have never experienced any such complications of trichlorethylene anaesthesia, although we have eschewed the use of the closed system with this drug since 1943.

Practical Advantages and Disadvantages

As already stated, trichlorethylene has a high analgesic value and a low rate of excretion, which properties permit small quantities of the drug to be used and allow its complete withdrawal early in the anaesthesia. Once narcosis has been established gas-and-oxygen anaesthesia can be administered, reinforced with trichlorethylene given in this way. The drug is non-inflammable, only slightly irritant, inexpensive, and possesses a pleasant smell. Recovery time is short if it is properly administered, and

there is no doubt that post-anaesthetic vomiting is infrequent. Vomiting is certainly less common than after ether anaesthesia, when the patient's recovery is in addition often attended with the unpleasant taste and smell of the anaesthetic.

Trichlorethylene does not produce good muscular relaxation and should never be employed with this object. Its low volatility demands some form of apparatus for its administration, the simplest being the Marrett type of inhaler, while it appears unwise to employ the drug in the closed-circuit machine. It is unsuitable for the maintenance of anaesthesia for children and in intrathoracic surgery, owing to the ease with which a severe tachypnoea is produced in both cases.

Uses

The three ways in which the agent may be used in modern anaesthetic practice are as follows.

Induction.—The non-irritant properties of trichlorethylene stamp it as an excellent anaesthetic for this purpose. Much larger amounts of the drug may be given for this short period than should be administered for the maintenance of anaesthesia. Endotracheal tubes can be conveniently passed "blind" after the establishment of narcosis with thiopentone, followed by the inhalation of about six breaths of a mixture containing N_2O , O_2 , trichlorethylene, and CO_2 .

Maintenance.—Trichlorethylene may be usefully employed as outlined above for all cases not requiring profound muscular relaxation. This embraces almost all operations outside the peritoneal cavity, and includes the bulk of neurosurgical, orthopaedic, ear-nose-and-throat, and ophthalmic practice.

Maintenance with Curare.—We have found trichlorethylene an excellent drug to use with curare for abdominal operations, and consider it preferable to ether, cyclopropane, or repeated doses of thiopentone (Ostlere, 1947). The anaesthesia is exactly the same as for cases not requiring muscular relaxation, curare being added intravenously when necessary.

Summary

A report is made of 40,000 administrations of trichlorethylene unattended by any fatality implicating the anaesthetic. The reported toxic effects of the drug are discussed, as well as its practical advantages and disadvantages. The three ways in which trichlorethylene may be used in modern anaesthetic practice are briefly described.

I am much indebted to Dr. C. Langton Hewer for his permission to publish this paper and for his assistance and encouragement during its preparation.

Addressing the Pharmaceutical Society of Great Britain on "Modern Knowledge of Protein Structure and its Pharmaceutical Significance," Dr. A. J. Albert said that Ernest Gale, of Cambridge, had discovered a Gram-positive organism, especially the cocci which are the most common source of glutamic acid for the synthesis of penicillin. This organism was prepared by removing from taking up this substance, and the organism was found to be also shown that the organism was not killed by penicillin. He had also shown that the organism was not killed by penicillin.

HOMOLOGOUS SERUM JAUNDICE

BY

K. B. SCOTT, M.R.C.S., D.R.C.O.G.

AND

GEOFFREY H. TOVEY, M.D.

Regional Blood Transfusion Officer, Southmead, Bristol

The following case history is reported to remind clinicians of the importance of considering homologous serum jaundice whenever a patient shows clinical signs of hepatitis

Case History

A primipara aged 19 was admitted to Southmead Hospital because of an abscess in the right breast. On admission she was seen to be jaundiced. The jaundice was said to have been present for 14 days. Its onset was accompanied by nausea and anorexia and had been preceded by diarrhoea and lassitude for three days. The stools had been pale and the urine dark. A diagnosis had been made at home of "catarrhal jaundice."

When admitted the patient's temperature was $101^{\circ} F$ ($38.3^{\circ} C.$), pulse 100, and respirations 20. Definite jaundice was present, and the liver was just palpable and tender. The stools were bulky and pale; the urine was dark and contained bile. Laboratory investigations agreed with a clinical diagnosis of hepatitis (blood count, mild hypochromic anaemia, reticulocytes 1%; van den Bergh reaction, biphasic; serum bilirubin, 1 mg. per 100 ml.; serum alkaline phosphatase, 22.8 units). The pyrexia subsided in 48 hours after incision and penicillin, and on a high-protein and high-carbohydrate diet the patient made a steady recovery. Her urine became free from bile 15 days after admission. The patient had been feeding a neighbouring baby as well as her own. Neither baby showed signs of jaundice.

Comments

It was discovered that because of a post-partum haemorrhage the patient had received a transfusion of two bottles of plasma and one bottle of group O Rh-negative blood 79 days before the onset of the jaundice. The relatively high incidence of hepatitis following plasma transfusion (5-10%) would make it seem probable, therefore, that this was a case of homologous serum jaundice.

Fortunately this patient made a complete recovery; but fatal cases have been reported (*British Medical Journal*, 1946, 2, 423), and the incidence of this complication following plasma or serum transfusions is great enough to constitute a grave deterrent to the transfusion of these fluids except for the express purpose of saving life.

The agent responsible for the hepatitis is thought to be carried by certain batches of plasma only. Batches at present issued may contain 500 or more bottles, and to minimize the risks of patients developing homologous serum jaundice following a plasma transfusion it is necessary that all remaining bottles of possible infective batches should be withdrawn from circulation as soon as a batch is suspected of carrying the infecting agent. The probability that this patient's jaundice was connected with the plasma transfusion had been overlooked by her doctor, and it seems likely that no more would have been heard of her jaundice had not the breast abscess supervened to bring her into hospital. It is possible that other cases of homologous serum jaundice are being missed in the same way, and we would stress the need to inquire into a history of a plasma, serum, or blood transfusion during the previous six months whenever a patient shows signs suggestive of hepatitis. Details of cases with a transfusion history should be brought to the notice of the regional blood transfusion officer so that these officers in all other regions may be informed of the serial number of the offending batch or batches and may take steps to withdraw from

hospital stores all remaining bottles. We are reminded, of course, of the great importance of clearly and accurately recording in the patient's notes the batch numbers of all infusion fluids given, for without a record of these numbers it is not possible to detect and withdraw from circulation the infected batches.

We are indebted to Dr. F. J. W. Lewis for the laboratory investigations.

HOMOLOGOUS SERUM JAUNDICE IN INFANCY

BY

JOHN APLEY, M.D., M.R.C.P.

AND

HUGH R. E. WALLIS, M.B., M.R.C.P., D.C.H.

(From the Children's Hospital, Bristol)

Indications for intravenous plasma therapy in paediatric practice are many. Since plasma possesses all the therapeutic properties of whole blood, except those conferred by the red cells, it is especially indicated in shock, thrombocytopenia and in hypoproteinaemia. In practice it is widely employed in the treatment of such conditions as burns and severe gastro-intestinal affections. Despite its widespread use, the complications and sequelae of plasma therapy in infancy are surprisingly uncommon; homologous serum jaundice, for example, appears to be extremely rare. We have been able to discover only one possible case in the literature (Scheinberg *et al.*, 1947), though another more fully substantiated case, following not plasma but blood transfusion in an infant, has recently been described (Bruyn, 1947). In later childhood, however, jaundice has followed the use of convalescent serum in several instances (Probert, 1938; Beeson *et al.*, 1944), while in adults it is a common complication of plasma therapy (*British Medical Journal*, 1946, 2, 423), occurring in 7.3% of cases in one large series (Spurling *et al.*, 1946). Various explanations may be advanced for the relatively low frequency of occurrence in infancy: a temporary passive immunity to the causative virus may be present at this period of life, hepatitis may occur but remain symptomless, or jaundice in infants may fail to be related with previous transfusion treatment. The history of the recognition of the condition in adults suggests that the last possibility is not unlikely to prove correct. For in reason two cases of fatal homologous serum jaundice occurring in infants are recorded, together with an inquiry to determine the incidence of this sequel after transfusion with reconstituted dried plasma.

Case 1

T.B., a male child who had never been inoculated or vaccinated, had had no illness until the age of 7 months. He was admitted to hospital with bronchopneumonia. He was treated with sulphathiazole and recovered from the pneumonia, but before discharge developed diarrhoea and vomiting. With these he became so severely dehydrated that he was treated with intravenous fluids, including reconstituted pooled plasma 20 ml. on each of two occasions, with an interval of six days, and subsequently made an uneventful recovery.

Four months later, at the age of 1 year, he was admitted to another hospital. He had been sleepy and jaundiced for two days. He had not vomited, though his appetite was poor, and his motions had been pale. On examination he was jaundiced and comatose. The pupils were pin-point but reacted to light. There was no neck rigidity. The liver was palpable one fingerbreadth below the costal margin. His temperature was 98.4° F.

(36.9° C.) on admission, but later in the illness it rose to 102° F. (38.9° C.). Coma continued for two days, and convulsive movements occurred occasionally. The child died after four days' illness.

The interval between the first infusion of plasma and the onset of jaundice was 122 days.

Necropsy Findings.—A post-mortem examination was carried out 60 hours after death. The child appeared plump and was moderately jaundiced. There were no haemorrhages on the body surface. Abnormal findings were as follows. *Lungs*: A small number of recent haemorrhages had occurred into the parenchyma posteriorly on both sides. The *spleen* was slightly enlarged (weight, 25 g.), and on section the pulp was firm and the surface flat. *Small intestine*: Peyer's patches appeared hyperaemic but were not ulcerated. The *kidneys* were very pale, but histological study showed no change in architecture. The *gall-bladder* contained some rather pale bile which was easily expressed into the duodenum. The *liver* showed some post-mortem hypostases. It was of normal size (weight, 350 g.), and the surface was smooth and pale yellow in colour. On section the liver tissue was firm, appeared extremely fatty, and was slightly jaundiced. No haemorrhages were seen. The bile ducts were not dilated.

Histology.—Unfortunately, post-mortem changes obscured the histological picture, but despite the short history of illness there was subacute hepatic necrosis with a lymphocytic cellular infiltration around the portal areas. The number of recognizable liver cells was greatly reduced, and most of the survivors contained fat vacuoles. The bile ducts were unaffected; they were not dilated, and contained no bile thrombi. A frozen section confirmed the impression that all the surviving liver cells were heavily laden with fat.

Case 2

S.J., a female child, had had no illnesses until she was 11 weeks old, when she developed diarrhoea and vomiting, and was admitted to hospital. She was severely dehydrated, and was at once given intravenous saline and dextrose with 200 ml. of reconstituted pooled plasma. She recovered and was discharged well after two weeks. Six weeks later she began to pass frequent stools. After five days her urine was noticed to be bright yellow and she started vomiting. Next day she became jaundiced and was readmitted to hospital. On admission she was slightly jaundiced, but well nourished and not dehydrated. No other abnormality was noted. Two days later she had two convulsions and vomited some blood. Next day the convulsions became more severe and frequent, and she died.

The interval between the infusion of plasma and the onset of jaundice was 63 days.

Necropsy Findings.—A post-mortem examination was carried out three hours after death. The infant appeared well nourished, and there was slight jaundice with some cyanosis. No superficial haemorrhages were seen. Abnormal findings were as follows. In the *lungs* a small number of subpleural haemorrhages were present, and there were some small foci of collapse but no consolidation. The *spleen* was dark red in colour, and was enlarged to three times the normal size; histologically it showed only venous congestion. The *liver* was smaller than normal, with a smooth mottled yellow surface.

Histology.—Sections from the left and right lobes of the liver showed a uniform degree of subacute necrosis. There was almost complete disappearance of the columns of liver cells, only a few islands of extremely fatty liver cells surviving in places. The liver sinusoids were intact and there did not seem to be any gross haemorrhages. The material between the sinusoids consisted of amorphous debris, with a cellular infiltration composed partly of polymorphonuclear leucocytes but chiefly of mononuclear cells. There was some early bile-duct proliferation, but no evidence of obstruction of any of the bile ducts.

Comment

The diagnosis of homologous serum jaundice in these two cases seems reasonably certain. The intervals between

the administration of plasma and the occurrence of jaundice (122 days and 63 days, respectively) fall within the accepted limits. There was no history of contact with patients suffering from infective hepatitis. Unfortunately, it proved impossible to trace other patients who had been treated with reconstituted plasma from the batches used in these two cases. Histologically the picture was the usual one of subacute hepatic necrosis.

An attempt was made to ascertain the incidence of homologous serum jaundice in babies treated with plasma intravenously. Of 39 babies under 18 months old treated with reconstituted dried pooled plasma 26 survived the initial illness; among these were the two cases described above. Questionnaires were sent to the parents of the remaining 24 after an interval of six months or more; 17 replies were received, and no further cases of jaundice were brought to light. Unfortunately, on the available material, only a small and entirely inadequate series of control cases could be investigated. Of 18 babies in the same age group as those previously described, and treated during the same period with whole blood or saline intravenously, 12 survived. Questionnaires were sent to their parents, but only five replies were received. Among these there was no report of the occurrence of jaundice.

Summary

Two fatal cases of homologous serum jaundice in infancy are described. One child developed jaundice 63 days after plasma infusion, and died at the age of 5 months, after a short illness characterized by vomiting and convulsions. The other child was 1 year old when jaundice developed 122 days after infusion; he died after four days' illness, having been comatose for two days.

No other cases of jaundice could be traced in 17 babies who had also been treated with intravenous plasma, or in five babies treated with intravenous saline or whole blood.

It seems possible that homologous serum jaundice in infancy may go unrecognized, just as it did until recently in adults, because of the long incubation period. The present investigation into incidence, though inadequate, is reported in the hope that it will stimulate further reviews based on the systematic follow-up of cases treated with plasma; by this means more substantial evidence of the real incidence of homologous serum jaundice in infancy may become available.

We are indebted to Prof. C. Bruce Perry for permission to record these cases and for his continued interest and encouragement. To Prof. T. F. Hewer our thanks are due for the necropsy reports.

The 1946 Year Book of General Therapeutics, November, 1945, 1946, 1947, edited by Oscar W. Bethea (Year Book Publishers, Chicago, \$3.75; H. K. Lewis, London, 21s.) is a well-selected summary of current medical literature and gives a concise and balanced review of recent progress in therapeutics. The summaries are a sample of some of the newer sulphonamides likely to be of value in the treatment of the common infections. The treatment of barbiturate poisoning with amphetamine and the treatment of allergic disorders with "benadryl" are also mentioned. The Year Book is a valuable reference work for the physician and the pharmacist. The Year Book is published by the American Medical Association and is published by the editorial footnotes.

Medical Memoranda

Traumatic Delayed Rupture of the Gall-bladder in a Child Aged 9

Traumatic rupture of the gall-bladder is an injury of considerable rarity. Usually it is found in association with other abdominal injuries, these being of such a nature as to overshadow the biliary lesion. The following case, though not unique, is thought to be of sufficient interest to warrant recording.

CASE REPORT

A boy aged 9 years was admitted to hospital on July 29, 1946. Two days before admission he fell while attempting to jump from a stationary railway truck on to the embankment. He was unconscious for about half an hour, after which he was removed to a local hospital, where he regained consciousness. His condition was then one of mild shock, accompanied by vomiting. He was complaining of vague abdominal pain, and slight abdominal rigidity was present. The usual measures to combat shock resulted in marked improvement in his general condition, which remained satisfactory until the following evening, when he again complained of vague abdominal pain. On this account, and in view of the probability of laparotomy being necessary, he was transferred to a larger hospital.

On examination the child did not appear shocked and lay quiet at ease while being examined. Abdominal distension was not present, but on palpating the abdomen there was generalized tenderness, maximal over the upper part of the right rectus muscle. Rigidity and "rebound tenderness" were absent, and there was no evidence of free fluid in the abdomen. On rectal examination the boy complained of pain about the umbilicus; otherwise nothing abnormal was detected. The pulse rate was 110 and the temperature 98° F. (36.7° C.). A tentative diagnosis of retroperitoneal haematoma was made.

Throughout the next two days his general condition remained excellent, the pulse being about 100 and the temperature varied between 98° and 100° F. (36.7° and 37.8° C.). This low-grade pyrexia was taken to indicate absorption from a retroperitoneal haematoma, and signs of peritonitis were still absent.

On July 31 the boy's condition suddenly deteriorated. He complained of severe abdominal pain and signs of shock were evident. He vomited three times within half an hour, the vomitus consisted of white frothy material. Abdominal examination revealed rigidity of the right rectus muscle and dullness of the right flank. Laparotomy was now considered necessary.

Operation.—The abdomen was entered by the right paramedian route. About 17 oz. (480 ml.) of bile-stained fluid was present in the peritoneal cavity. This fluid was removed, and on exploring the abdomen a hole measuring about 1/4 in. (6 mm.) in length was found in the fundus of the gall-bladder. Signs of inflammation were not evident in the organ, and although the edges of the hole were discoloured the perforation appeared to be of recent origin. There was no lymph exudate or any evidence of adhesions to surrounding structures. The small bowel was slightly dilated but otherwise normal. Drainage of the gall-bladder was effected through the hole by means of a fine rubber tube, and that of the associated abscess by a "cigarette" drain. The abdomen was closed around the drains.

No organisms were seen on microscopical examination of smears, preparations, and culture of the bile-stained fluid from the abdomen; showed no bacterial growth.

Routine post-operative measures were employed to combat shock, and within twelve hours the patient's general condition was satisfactory. Convalescence was uninterrupted and the child was discharged well after twenty-one days.

In the opening remarks I inferred that this case was unique. Two similar cases are recorded—one by Siegel (1909) and a second by Hicks (1944). The latter case was one of perforation of the gall-bladder in a child aged 3 years; in the former, perforation occurred eight days after injury and was explained as being a distension gangrene due to secondary infection when the cystic duct became occluded with blood clot.

I should like to express my thanks to Mr. Matthew White for permission to record this case.

DAVID FREW COULTER, M.B.
 Resident Assistant Surgeon, Royal Hospital
 for Sick Children, Glasgow.

Reviews

BIOCHEMICAL BOUNDARIES

Vitamins and Hormones. Vol. IV. Edited by Robert S. Harris and Kenneth V. Thimann. (Pp. 406. 56.80.) New York: Academic Press Inc. 1946.

Annual Review of Biochemistry. Vol. XVI. Editor, J. Murray Luck; Associate editors, Hubert S. Loring and Gordon Mackinney. (Pp. 740. 36s.) California: Stanford University P.O. Annual Reviews, Inc. London: H. K. Lewis and Co.

These volumes are excellent specimens of the survey work—conducted along two somewhat different approaches—done by our American colleagues in so many fields, and in few so effectively as in biochemistry with its many adjacent scientific territories, from pathology to organic chemistry, from animal nutrition to marine bacteriology, from endocrinology to chemotherapy. So useful are the series to which these two volumes are the latest additions that they arouse once more the gravest misgiving about the present indiscriminate slashing at book imports imposed under the banner of crisis economy and dollar savings. The unprotected scientific worker who cannot have such books on more or less permanent loan from his institution or a public library (and the number who can are negligible) is irretrievably handicapped in the pursuit of his own immediate researches, and the results of his work and their practical application may be forestalled by those who are not obstructed by unimaginative measures of pseudo-economy. Such measures must have a directly adverse effect on the "export drive," which the scientific worker's sacrifices are designed to further.

For example, can the agricultural biochemist concerned with problems of milk production remain ignorant of Housay's survey of "The Thyroid and Diabetes," or Reineke's of "Thyroactive Iodinated Proteins" (*Vitamins and Hormones*, IV)? How can the physician—a contributor to national health and therefore to morale and output—wishing to study research on blood dyscrasias fail to profit by reading T. D. Spies's review of "The Use of Pteroylglutamic Acid in Clinical Studies" (*Annual Review*, XVI) or Pfiffner and Hogan's article on "The Newer Hematopoietic Factors of the Vitamin B Complex"? The answer to these questions must be as obvious to every research worker as it is apparently obscure to an administration still effectively blind to the value of scientific research.

These volumes maintain the high standards we have come to expect of them. It is a pleasure to note that the *Annual Review*, nearly 60 pages longer than the 1946 volume, maintains its partly international character and that British authorities have contributed three out of the 25 chapters; the remainder, apart from one Canadian and one Swedish contribution, all come from the U.S.A. The authors of these 25 chapters cover every aspect of biochemistry with a great array of concise and carefully classified information based on the most recently published papers in every part of the world. Most of the 31 authors are on university staffs, but six are working in independent research institutions and five in industry. As before, the editors have chosen with tact and discrimination, and the contributors have fully justified their selection.

Vitamins and Hormones maintains equally well its somewhat different, and much younger, tradition. The physical, if not the spiritual, descendant of the pre-war *Ergebnisse der Vitamin und Hormonforschungen*, of which only two volumes ever appeared, it has now settled well into its stride. Biochemical and endocrinological topics are considered in a more detailed and more critical manner than in the *Annual Review*; thus a smaller number of subjects can be covered annually, so that a more cunning and discriminatory selection has to be made. And very well made it is again. Though choice of the most practical review in this volume—at any rate from the point of view of applied medicine—must be between F. W. Clements's "Manifestations of Nutritional Deficiency in Infants" and Roy Hertz's short account of the "Effect of B Vitamins on the Endocrinological Aspects of Reproduction," the laboratory worker may be more interested in Sidney A. Thayer's "Methods of Bioassay of Animal Hormones," a

fairly complete survey, albeit in some places rather superficial. Readers in every branch of medical science, however, should make it a duty to read—and for the discriminating it will become a pleasure to re-read—the masterly and fascinating essay by Howard A. Schneider, of the Rockefeller Institute, on "Nutrition and Resistance to Infection: the Strategic Situation." It is as pretty a piece of scientific writing, as cogent a piece of constructive logical thinking, as has come my way for many a long year.

A. L. BACHARACH.

SEXUAL PERVERSION

Sinn und Gehalt der Sexuellen Perversionen. By M. Boss. (Pp. 130. 12 Swiss francs.) Berne: Medizinischer Verlag Hans Huber. 1947.

The main part of this small book on the meaning and idea of the sexual perversions consists of eight full case histories each describing the personality of a pervers, his development, and symptoms. The history of these patients, some of whom had been treated on analytical lines, and the interpretation of their lifelong conflicts are fine psychological and biographical writing by a humane and understanding physician. Boss's argument is a battle on two fronts: against Freud's explanation of perversions as regression to a childish stage of sex development, and against the view of certain Continental writers who judge perverse behaviour as depraved and degraded substitutes for a broken sex life. In contrast Boss points to the positive human values hidden even under absurd deviations of erotic fulfilment, only if we recognize these values can we hope to understand the patient and help him towards normality. Boss's ideas represent an important development in analytical psychopathology. Unfortunately they are cloaked in the heavy language of "existentialism," which seems to resist transcription into plain English.

W. MAYER-GROSS.

SIXTEENTH-CENTURY PROPHYLAXIS

Una Epidemia de Peste Bubonica en el Siglo XVI. By Dr. Don Jose Viñes Ibarrola. (Pp. 133. No price given.) Pamplona: Editorial Aramburu. 1947.

The Chief Health Officer of Navarra has a triple object in describing this epidemic of bubonic plague in the sixteenth century. He uses many contemporary documents from the municipal archives of Pampeluna to show that this outbreak was not associated with an epizootic, that the chain of infection was patient, fomite, flea, healthy person, and that the lack of bacteriological knowledge did not prevent Joan de Lortia, with his 42 years' experience of plague, from introducing measures as effective as those taken against typhus before the use of D.D.T.

Dr. Ibarrola gives an intimate picture of domestic conditions in a European city of 30,000 inhabitants in 1599 and shows how the control of plague in Pampeluna was a local achievement, for, whereas its morbidity there was 1.14%, that of the epidemic at Santander (1596) was 45.93%. This success was due not only to the rapid organization of a complete plan of control under an experienced staff which included doctors, nurses, disinfectors, undertakers, and guards, but to the recognition, so rare for the period, that there was no visitation of divine wrath but a contagious disease which could be traced to individuals and fomites. Preventive measures included a daily muster of the entire population, notification of the sick and their immediate examination and isolation, isolation and quarantine of all contacts, boiling all suspected clothing, terminal disinfection, sanitary inspection of houses and streets, supervised disinfection of houses, destruction of bedding by fire, burying excreta and dressings under lime, and even the isolation of drinking-vessels. There is no reference to dead rats, and the available statistics of topographical and familial incidence, together with details of incubation periods, all support the opinion that the rat took no part in this epidemic. The author considers that, even after the arrival in Europe of *R. norvegicus* in 1727, many epidemics have occurred without the intermediation of that animal and that far too much attention has been given to this mode of spread. The absence of detailed references seriously diminishes the value of this book.

J. J. KEEVIL.

RECENT PAEDIATRICS

The 1946 Year Book of Pediatrics. Edited by Isaac A. Abt, D.Sc., M.D., with the collaboration of Arthur F. Abt, M.D. (Pp. 464; illustrated. \$3.75 or 21s.) Chicago: The Year Book Publishers Inc. London: H. K. Lewis and Co. 1946.

Once again the two Professors Abt, of Chicago, have reviewed the literature to produce the *1946 Year Book of Pediatrics*. Welcome signs suggest that more European publications are available, and there is a gratifying number of abstracts based on papers in the *British Archives of Disease in Childhood*. The authors of one Dutch paper quoted discuss what are termed "pontile tumours": surely the more usual topographical adjective is "pontine." But it must in fairness be said that random sampling has revealed no other obvious errors. Streptomycin is briefly mentioned in the official statement issued by the special committee of the National Research Council and referred to in other sections for its use in tuberculous meningitis and as a urinary antiseptic. The illustrations have been carefully chosen and most have been well reproduced. As usual, the editorial comments are a valuable part of the book, and there is a good subject index. The now familiar "quiz" of twenty questions on the cover proved too difficult for one reader at least to obtain a pass mark, which indicates, among other things, the vast amount of new paediatric literature being published each year.

A. MONCRIEFF.

ATOMIC ENERGY

Atomic Energy. By R. R. Nimmo, M.Sc., Ph.D. (Pp. 201; 45 figures. 9s. 6d.) London: Pilot Press. 1947.

What is Atomic Energy? By K. Mendelssohn, M.A., Ph.D., F.Inst.P. (Pp. 180; 37 figures. 6s.) London: Sigma Books. 1947.

Atomic energy is an intrinsically difficult subject and one which cannot be understood in any serious sense without some effort of apprehension. On the other hand, it is not only of obvious and general importance, but of particular interest to medical and biological science because of the increased supplies of radioactive materials which are already becoming available and the health problems to which it gives rise in peace and to an infinitely greater extent perhaps in war. There is also the natural interest of all scientific workers that research should not be allowed to suffer from other considerations. Any book which can help the doctor in a first approach to these problems is therefore to be welcomed. The writers of each of these volumes is a professional physicist, and the choice between them must be largely dictated by the amount of effort which the individual reader is willing to make.

Dr Nimmo's book is the more substantial of the two, and has been planned on the basis that all frills and inessentials are sternly avoided. The result is that the educated reader who begins at the beginning and reads steadily and carefully to the end, stopping occasionally to think and to undertake a little personal exercise, will emerge with some genuine understanding of the sequence of discovery which led to the release of atomic energy, as well as practical methods of research, and will be left with a reasonably solid foundation on to which further reading can usefully be grafted. On the other hand, there is little titivation, for both writing and illustration are utilitarian and restricted to the purpose of the book.

Dr Mendelssohn is also serious in his intention, but offers more by way of bait. Stylistically, Nimmo's opening statement that "in the middle ages the transmutation of metals was widely accepted as a possibility" is paralleled by the more flamboyant, "Since the dawn of history man's mind has contemplated the variety of materials which surround him and which have played an ever increasing part in his daily life." Pictorially, the illustrations are rather of the kind favoured as "visual aids." In addition he has somewhat less space at his disposal. The result, as might be expected, is a book which offers less reward for a correspondingly less expenditure of energy. Both books are good of their kind, and the choice between them must depend on the time and manner of reading. In a train or in a crowded room one might prefer Mendelssohn; in more favourable conditions, Nimmo.

A. W. HASLET.

BOOKS RECEIVED

[Review is not precluded by notice here of books recently received]

Hearing Aids. By Hallowell Davis et al. (Pp. 197. 11s. 6d.) London: Geoffrey Cumberlege. 1947.

An account of experiments carried out in the U.S.A. to determine a suitable design for hearing-aids.

A Handbook for the Diagnosis of Cancer of the Uterus by the Use of Vaginal Smears. By Olive Gates, M.D., and Shiel Warren, M.D. (Pp. not numbered. 22s.) London: Geoffrey Cumberlege. 1947.

Profusely illustrated with photomicrographs.

The Conquest of Brain Mysteries. By George Bankoff, M.T. F.R.C.S. (Pp. 174. 6s.) London: Macdonald. 1947.

Psychology and psychiatry for the layman.

La Rage. By P. Remlinger and J. Bailly. (Pp. 193. 350 francs.) Paris: Librairie Maloine. 1947.

A monograph, including historical details, on rabies.

Contribution à l'Etude Physique, Physiologique, et Clinique de l'Electro-Choc. By Marcel Lapierre and Jacques Rondepierre. 2nd ed. (Pp. 374. 380 francs.) Paris: Librairie Maloine. 1947.

A general account of electric convulsion therapy based on the authors' experience.

Le Médecin à la Recherche d'une Doctrine. By Dr. L. A. Roussau and Jean Tétou. (Pp. 190. 153 francs.) Paris: Librairie Maloine. 1947.

Essays on the art of medicine.

Homéopathie. By J. Tétou. 2nd ed. (Pp. 202. 200 francs.) Paris: Librairie Maloine. 1947.

A manual of homoeopathic therapy.

Synopsis of Neuropsychiatry. By Lowell S. Selling, M.D. Ph.D., Dr.P.H., F.A.C.P. 2nd ed. (Pp. 561. 32s. 6d.) London: Henry Kimpton. 1947.

A summarized account of neurology and psychiatry.

Recherches sur la Sclérose en Plaques. By M. Laignel-Lavastine and N. T. Korsicss. 3rd ed. (Pp. 511. 850 francs.) Paris: Librairie Maloine. 1947.

An investigation into disseminated sclerosis, with many case histories.

Textbook of Embryology. By H. E. Hordan, M.A., Ph.D. Sc.D., and J. E. Kindred, M.A., Ph.D. 5th ed. (Pp. 613. N. price.) New York and London: D. Appleton-Century. 1948.

Intended primarily for medical students.

Ergametrie. By Gabriel Bidou. (Pp. 102. 250 francs.) Paris: Librairie Maloine. 1947.

A monograph on the measurement of work done by the human subject.

Gynécologie Médicale. By J. E. Mareel and Maurice Fabrè. (Pp. 733. 2,140 francs, paper covers; 2,540 francs, cardboard covers.) Paris: Librairie Maloine. 1947.

A textbook of gynaecology.

Gardiner's Handbook of Skin Diseases. Revised by John Kinnear, O.B.E., T.D., M.D., M.R.C.P., D.L. 5th ed. (Pp. 251s.) Edinburgh: E. and S. Livingstone. 1948.

A manual with many illustrations for students and general practitioners.

The Essentials of Modern Surgery. Edited by R. M. Handfield Jones, M.C., M.S., F.R.C.S., and A. E. Porritt, C.B.E., M.A., M.C. F.R.C.S. 3rd ed. (Pp. 1,256. 50s.) Edinburgh: E. and S. Livingstone. 1948.

A textbook of clinical surgery intended primarily for students and general practitioners.

Textbook of General Surgery. By Warren H. Cole, M.I. F.A.C.S., and Robert Elman, M.D., F.A.C.S. 5th ed. (Pp. 1,111. \$11.00.) New York and London: D. Appleton-Century. 1948.

A textbook for student and general practitioner.

BRITISH MEDICAL JOURNAL

LONDON

SATURDAY JANUARY 31 1948

THE RIGHT TO ATTACK

"Don't be impudent" was the reply given by Mr. Bevan on Dec. 3 to a sensible question quietly put to him by a member of the Negotiating Committee who is still an independent practitioner. When asked another question on compensation Mr. Bevan said the Committee should be careful not to drive him too far on the question of compensation, because the profession had no real right to it and towards the end of the meeting he said that if there were not enough practitioners in the Service two years after the appointed day there would be a "sharp diminution" in the capitation fee. We are not drawing attention to these facts in order to score off Mr. Bevan or to stir up partisan prejudice against him. These incidents were, if true, uncomfortable examples of his intransigence. But what is important is the danger to medicine illustrated by the present Minister's behaviour. We do not stress this because the vehicle of the behaviour is Mr. Bevan: after all, he won't be Minister of Health for ever; in fact, the present Government has a renewed lease of life in the next election Mr. Bevan may well be a candidate for much higher office than that of Minister of Health. The danger lies in the all-powerful control of the medical profession by any political office-holder, in the nationalization of medicine, in the subordination of medical men to the State machine. If a Minister can treat independent members of a learned profession in the way described when he is supposed to be negotiating with them, what treatment may professional representatives at some future date expect to receive at the hands of an ambitious politician who has complete control over all aspects of medical life—who owns all the hospitals, all the practices, employs all medical men and women, and who can alter their lives and livelihoods by the issue of Orders and Regulations? The doctrinaire theorist, seeing nothing but the supposed virtues of plans and planning, devises State schemes attractive in their apparent simplicity, and satisfying to an obsessional demand for administrative tidiness. The doctrinaire talks about the State as if it embodied all the wisdom and virtue that very few individual men have ever possessed; and with the decay of the old faiths the State is now worshipped as a god and as a god whose principal attribute is power. The doctrinaire, sincere but woolly-headed idealist, forgets that the State is a group of politicians holding power, forgets that a State Medical Service means a Service organized and controlled by an administrative Department at the head

of which is a politician who uses his office primarily as a method of pursuing political ends.

We have always believed, and have said so, that Mr. Bevan has wished to provide the country with improved medical services. We have hitherto believed him when he said that in doing this he genuinely wished to secure the co-operation of the medical men and women of this country—or at least of the majority of them, for there will always be a minority dissatisfied with whatever happens. We may continue to believe that Mr. Bevan wishes to provide this country with improved medical services, though we may have grave doubts whether his Act provides a real opportunity for doing this. But we begin to doubt his assertion that he desires the co-operation of the medical profession, because—to use a current vulgarity—he seems in recent months to have leaned over backwards to avoid obtaining this. Mr. Bevan the politician has got the better of Mr. Bevan the Minister of Health.

The keynote to his present tune was sounded by the *Tribune*. If Mr. Bevan was to give way to a "reactionary profession" he would desert the sacred cause of socialism—would endanger, may we suggest, his place at the head of the keep-left movement. In his letter to the three Presidents in January of last year he opened the door for negotiations on the Act, and it was clear to him, as to everyone else, that those negotiations were for the purpose of amending the Act, as the last plebiscite said "No" to negotiations on Regulations. The negotiations started by Mr. Bevan between the officers of the Ministry of Health and the Negotiating Committee and its various subcommittees were rendered farcical by Mr. Bevan's conduct of the final discussion on Dec. 2 and 3. He chose the method of humiliation, not of conciliation. The Committee might with justice have addressed to Mr. Bevan these words of Benjamin Franklin, "Those who would give up essential liberty to purchase a little temporary safety deserve neither liberty nor safety"—to borrow from a forthright editorial in the current issue of the *Medical Press*.

We should not, however, allow ourselves to become too indignant about the way we have been treated by one man—even though that one man is given by the National Health Service Act supreme and absolute authority over medical men and women. As doctors we can allow for the explosiveness of a fervent character. But the whole episode has this one important lesson which as a profession we must take to heart and mind—the dangers of monopolistic control in the hands of one man over the whole of the medical profession. In a leading article nearly four years ago¹ we drew attention to the views of some of the planners of medicine and the forces behind them. In a pamphlet on the National Health Service White Paper the Communist Party then stated: "The Government's proposals have been published after a very great deal of pressure from the Labour and Communist Parties, Co-operative Organizations and Trade Unions, and health workers' organizations, such as the Socialist Medical Association." "Control," the Communist pamphlet stated, "will be in the hands of the State and local authorities . . . and standards will be laid down." P.E.P., in its commentary

¹ *British Medical Journal*, 1944, 2, 47.

on the same White Paper, put in a nutshell the real case against a State Medical Service in these words:

"Much will depend upon the attitude of the Treasury, the effectiveness of the Central Health Services Council, the personality of the Minister, the alertness of his officials, and the political complexion of Parliament."

We agree with P.E.P. that much—far too much—will depend upon these key features in the National Health Service, and think it would be deplorable if the medical profession and the public were ever to be placed in a position of dependence upon these things. Our esteemed contemporary, the *Lancet*, does its best to support the Minister in its advocacy of the National Health Service Act. While we respect the sincerity with which its views are sustained we believe we are not doing it an injustice in detecting in its columns the same doctrinaire worship of State power that is the modern fashion. A Minister, the *Lancet* writes, "must hold powers of negative direction . . . and we have never been persuaded that the exercise of these powers would ever involve any substantial hardship." In comparing the opposition of the medical profession with the opposition to the building of new towns the *Lancet* observes that the result of such opposition is "that no new town can ever be built unless *ruthless authority* is exerted" (our italics). "*Ruthless authority*" is a less euphemistic expression than "compulsory co-operation." And the *Lancet* says this, apparently with approval: "If the profession cannot find itself ways to prevent grossly unfair certification by a proportion of its members some subsequent Government may indeed feel obliged to safeguard these funds [public funds] by changing capitation fees into salaries." Because some men offend, all men are to be treated as if they were offenders—a curious argument. Is this the real reason why Mr. Bevan insists upon the new Health Service starting on July 5 although he is not yet ready with plans for the building and setting up of his key structure for the general practitioner service—namely, health centres—and is this the real reason for the universal basic salary?

The plebiscite form is to-day being posted to all practitioners in Britain. The B.M.A. Council and the I.A.C. have expressed their attitude to the Act in its present form in short statements published elsewhere in this *Journal*. Their joint view is that the Act as it stands is harmful to medicine. The Council of the Royal College of Surgeons passed the following resolution last week:

The Council of the Royal College of Surgeons of England, while believing that every member of the profession must act according to his conscience in deciding whether to accept service under the National Health Service Act, is of opinion that fellows and members of the College should do all in their power to maintain the unity of the profession in its endeavour to attain the highest ideals of service.

This call for unity could not have been more timely. General practitioners have been uneasy about the attempts of Mr. Bevan to divide the consultants against them. Mr. Bevan provided in his Act a special and favoured place for the teaching hospitals. Last month he offered

consultants an assurance that seemed to be financially tempting—for example, by suggesting that he would aside in State hospitals beds with no ceiling on fees. It is therefore encouraging that the honorary consultant staff of the London Hospital—the largest teaching hospital in London—should pass unanimously the two following resolutions at a meeting of the London Hospital Medical Council on Jan. 21:

(1) that in the view of this Council no step which lead towards whole-time State salaried medical service would be in the best interests of the community;

(2) that in the opinion of this Council consultants and specialists should not take service under the new Health Act until agreement has been reached with the profession as a whole.

On Jan. 26 the medical staff of St. George's Hospital discussed the present Act by 28 votes to 1, and by 21 votes to 4 agreed to abide by the majority decision in the plebiscite. On Jan. 21 the Faculty of the Bristol Royal Hospital, the registrars included, discussed the National Health Service Act. A secret ballot was held: out of 60 medical men present, 56 voted not to take part in the Service under the Act; only 2 voted for service, and 2 remained undecided. The Council of the Royal College of Surgeons has asked for unity. Three important teaching hospitals by resolution have paved the way, and should encourage those who may still be undecided or fearful.

Those who still fear that to say No is to oppose the will of the majority should take heart from a recent statement of the Lord President of the Council, Mr. Herbert Morrison²:

"Particularly would I add the right to attack and for the Government of the day. That, perhaps, is the biggest single test of democracy. To go for the Government of the day is a sacred British possession. A Government which tries to take that from you is a danger and a menace, and you had better get rid of it."

Mr. Morrison and Mr. Bevan have both reminded of our right to individual and collective opposition. Every doctor in the country should now follow the dictate of conscience in answering the questions on the plebiscite form.

CENSORSHIP

The word "freedom," like the word "democracy," may become so abused that what it stands for in these days is becoming lost sight of. But the coin is still there, even though its image and superscription have been rubbed away by rough usage. It does not mean the abuse of liberty called licence, but it does—at least so we like to believe—still mean freedom of assembly, freedom of publication, and freedom to say Yes or No to questions put by free men to each other. These three freedoms are now being called in question. A short time ago the medical officers of one of His Majesty's armed Forces wanted to hold a meeting to discuss the National Health Service Act, and to hear the views of medical men not members of that Force. They were forbidden to hold this meeting and were

t allowed to listen to dangerous thoughts. A county medical officer of health recently instructed the public health officers on his staff not to take part or vote in a meeting held in their area to discuss the National Health Service Act. They were present but had to sit in enforced silence. These public health officers, so instructed, could not follow the example of the Willesden nurses who were instructed by the Medical Officer of Health for Willesden to join a trade union. The nurses resigned, and presumably had some safeguard in that there was an alternative open to them—to work elsewhere. It is intolerable that this sort of thing can happen in a country that in the past has been an example to the world in its fight for the essential freedoms of Western civilization, and which has just emerged, battered but victorious, from a war fought to preserve the freedoms won in the past.

We see in the above two examples denial of freedom of assembly, denial of freedom to vote according to conscience. The third threat has been the subject of correspondence in this *Journal* started in our issue of Dec. 27 by a letter from Mr. Johnston Abraham, followed by a letter by Mr. R. F. West, Chairman of the Medical Group of the Publishers Association. Distinguished medical men have taken up the theme in this week's correspondence columns. Mr. Johnston Abraham was, because of his experience with the Ministry of Education, anxious about the future publication of books written by medical men who, if working full-time in the new National Health Service, will be State servants. "The whole idea of such a censorship in civil life is inimical to freedom of thought." Mr. West drew attention to the following reply given by the Financial Secretary to the Treasury to a question asked in the House of Commons on Nov. 6 by Mr. Isaac J. Pitman.

A Crown servant must obtain the consent of the head of his Department for the publication of any work the subject matter of which is connected with his official duties or those of other public servants. . . . I understand that no rules have yet been made for employees of the new bodies set up under the National Health Service Act.

The question of censorship is as important as any of the present points of conflict between the Ministry and the profession about the National Health Service Act. If the necessary majority of Noes is obtained to justify collective opposition to Mr. Bevan's Act, and if negotiations are opened to secure amendments to that Act, it will be operative to see that some amendment is put in with regard to publication of books and of articles and letters in the medical press, whatever assurances the Minister of Health may yet give on this matter.

It is a common experience of the Editor of this *Journal* to be asked by medical men employed by local authorities to publish letters under a pseudonym. Assistant M.O.s, H. and deputy superintendents of hospitals have said in covering letters that if their legitimate criticisms are published under their name their security in the service would be threatened and their chances of promotion diminish to vanishing-point. The Editor, though reluctant to publish anonymous letters, has always met these requests. In a

leading article in 1943¹ we drew attention to the fact that no medical man in the service of the L.C.C. could submit for publication a scientific article or a letter without the permission of the Chief Medical Officer of the L.C.C. The L.C.C. subsequently amended its Standing Orders so as to allow medical men in its service to submit scientific articles without seeking the permission of the Chief Medical Officer, but at the same time so worded the new Order as to disallow the submission of letters or articles on other professional matters without such permission.

The Minister of Health has already secured in the Act freedom to withhold the report of the Central Health Services Council if it is in the public interest to do so. The public, of course, will have no opportunity of knowing whether or not it was in its interest to withhold publication. With more and more medical men employed whole-time in a State Medical Service, with, in fact, all the doctors receiving their remuneration from the public funds controlled by the Treasury, what freedom to publish not only scientific articles but articles on a whole range of professional matters will the medical employee of the State be likely to have? The correspondence columns of the *B.M.J.*, the open forum for the medical man to discuss fearlessly what he thinks about any aspect of professional work and life, will be filled with anonymous contributions, written by men who will not dare call their names their own. These fears may sound fanciful now, but if we passively allow our freedoms to be filched from us one by one, freedom of opinion and freedom of publication will disappear with the rest—in the public interest, no doubt, as interpreted by the owners of the State machine.

JUVENILE DELINQUENCY

The large increase in juvenile delinquency during the war and post-war years has once again drawn attention to this problem. Indeed it has been said that the vast majority not only of adult criminals but also of the unproductive and antisocial members of the community—the "drones" and "spivs" of whom we hear so much—come from the ranks of those who during childhood and adolescence were already recognized as incipient delinquents. Public opinion has now advanced well beyond the stage in which it was supposed that the only cure for the young offender was a strong dose of physical punishment. Educational and medical experts are agreed that each case needs individual study and an appropriately adapted treatment, in short, that the problem is to be solved only by a scientific approach.

British psychologists led the way in the scientific study of delinquency. The simple device of the control-group together with more objective methods of testing and assessing qualities of intelligence, temperament, and character helped to show that delinquency itself is not a simple clinical entity but a superficial symptom with a highly variable and complex causation—the resultant in most instances of a number of factors whose nature may differ widely from one case to another. The studies of Burt at Liverpool and in London were followed by the investigations of Healy and his colleagues in America, and the

¹ *British Medical Journal*, 1943, 1, 323.

essential causes of juvenile delinquency are now fairly well established. Most urgently needed are similar investigations into the efficacy of different methods of treatment as judged by the after-histories of cases of various types. Apart from a small number of follow-up inquiries carried out on delinquent cases first coming under observation in L.C.C. schools, comparatively little research of this kind has so far been undertaken in this country. Reports on the later careers of youths discharged from Home Office schools and other institutions are generally too vague and too meagre to yield a basis for practical measures. The obvious method, adopted in the London inquiries, is to follow the recognized statistical principles for calculating life tables and for determining survival rates or immunity rates after specified forms of treatment. In the London cases it was found that of persons "exposed to risk" during equal periods (15 years) as high a proportion as 40% succumbed among those who had been treated psychologically, either at child-guidance centres or elsewhere, while between 50 and 60% could be regarded as successes. Among cases of equal gravity that had received no special study or treatment the spontaneous recovery rate was just over 40%.

The same method of analysis has been employed on a far larger scale in an inquiry undertaken by the State Institute of Human Genetics in Sweden.¹ The material analysed consisted of cases recorded in the files of the Malmö Child Welfare Board over a period of 37 years—from 1903 to 1940. More than 2,300 children were divided into four main groups: children who had been brought before the juvenile court; children who had been found so delinquent that special measures were required for their correction; children who had come from bad homes and were guilty of some minor delinquency only; and non-delinquent children who had been removed from bad homes solely for preventive purposes. The last served as the control group. The after-history of each case was traced to the beginning of 1944. The requisite information was obtained from foster homes, welfare committees, the penal register, the police gazette, and all other relevant sources that were accessible. The investigation was mainly concerned with the "social prognosis" for such cases after the child reached adult life. The results have been expressed by calculating the "annual risk" and the "total risk" in regard to criminality, drunkenness, vagrancy, or the receipt of public assistance. The outlook in relation to crime, as might be anticipated, was worst for the court cases and for those removed for serious delinquency. In these two groups the frequency of criminal offences in later life was nearly twice as great as among those who had been removed from their homes as a protective measure only. On the other hand the incidence of vagrancy and appeals for poor relief differed but little from group to group. Vagrancy, in fact, was reported most often in the case of youths who had been transferred from poor or unsatisfactory homes to residential institutions.

It is reported on to observe that "if we are to understand the problem of delinquency, it is not enough to study the different manifestations of delinquency; we

must investigate the actual conditions under which the delinquents have grown up—particularly the conditions in the child's own home." Further information was therefore sought on the financial and social position of the family, the number of children in the household, and its general emotional and moral atmosphere; alcoholism, death or separation of the parents, illegitimacy of the child, and frequent changes in care or control were all noted. It was found that the children coming from homes in which the parents were drunkards or criminals were "especially liable to commit crime when grown up, or to turn into ne'er-do-wells and vagrants, requiring public assistance." On the other hand, no significant differences were found on comparing the after-histories of illegitimate children or children from broken homes with those of legitimate children coming from normal homes. Nor apparently did the child's own intelligence yield any definite indications of the probability of future relapses.

The material did not lend itself to any intensive study of the comparative merits of different modes of treatment. So far as could be discovered, neither the age at which the children were taken charge of nor the period of detention had any discernible influence on their later careers. The most significant feature for future prognosis was the type and frequency of the offences committed by the child when first brought under official notice. The whole investigation is one of the most extensive and elaborate within its own particular field, and might well serve as a model for inquiries into what is likely to prove an important branch of social medicine—namely, the statistical analysis of the life histories of different sections of the population judged from the standpoint of civic efficiency and mental health.

EXO-ERYTHROCYTIC FORMS OF MALARIA PARASITE

In the communication by Shortt, Garnham, and Malamez which we publish on p. 192 evidence of a convincing nature is at last brought forward that the cycle of development of the malaria parasite in the mammal is exactly analogous to that occurring in birds. The exo-erythrocytic forms in avian malaria were first described by James and Tate¹ in 1937 in association with *Plasmodium gallinaceum* in chickens: later Reichenow and Mudrow² showed that similar forms are to be found in *Plasmodium relictum* in the canary. Reichenow and Mudrow³ also described bodies in the endothelial cells in association with another avian infection, *Plasmodium praecox*, while Garnham similarly found bodies highly suggestive of an exo-erythrocytic stage in the life history of *Hepaticystes* (*Plasmodium kochi*).

That an exo-erythrocytic form must occur in association with human malarial infections seemed certain both from attempts at transmission of human malaria, from chemical therapeutic experiments, and from the fact that while human beings are infected both with *Plasmodium falciparum* and *P. vivax* the growth of *P. falciparum* successfully interferes with the further development of *P. vivax*, which finds difficulty in appearing in the blood so long as the body

¹ James, S. P., and Tate, P., *Nature*, 1937, 139, 545.

² Reichenow, E., and Mudrow, L., *Disch. Tropenmed. Z.*, 1943, 47, 239.

³ Reichenow, E., and Mudrow, L., *Arch. Protistenkunde*, 1946, 87, 101.

⁴ Garnham, P. C. C., *Trans. roy. Soc. trop. Med. Hyg.*, 1947, 40, 719.

s infected with *P. falciparum*, an instance of interference, a phenomenon well known in connexion with viruses. The demonstration of an exo-erythrocytic stage in a malaria parasite of the monkey will facilitate the search for such a stage in *falciparum* and vivax malarias of man and will serve to intensify the search for chemotherapeutic drugs which can act specifically on this exo-erythrocytic stage. If this stage can be successfully destroyed it will mean that the infection can be totally eradicated before it gives rise to any symptoms of ill-health.

INFECTIVE HEPATITIS AND POLIOMYELITIS IN FAMILIES

Two recent American papers on the epidemiology of infective hepatitis and poliomyelitis record intensive studies of affected families. Kunkel and Hoagland¹ investigated a New York family in which during five months nine out of the ten children suffered from infective hepatitis. Three had frank jaundice; in the other six the diagnosis was made on the symptomatology, aided in some cases by finding spider angiomas on the neck, shoulders, or arms, and also by biochemical tests. The tests used were the three which previous experience in the Rockefeller Hospital had shown to be the most reliable—namely, plasma bilirubin, bromsulphthalein retention, and thymol turbidity. The thymol turbidity test was of special value in confirming the diagnosis after recovery.

Infection was probably introduced into the family in October, 1945, by an elder brother who had a mild illness while on leave from a naval base where cases of infective hepatitis were occurring. Three children fell ill between Nov. 13 and 25, one on Dec. 22, four between Jan. 12 and 24, and one on Feb. 8—a series typical of the disease. There was gross overcrowding of the family's sleeping quarters, and the authors conclude that the mode of spread was by contact. In view of the demonstration by British and American workers that the infective agent is present in faeces they assume that faecal transmission was involved. The epidemiological evidence hardly justifies this assumption, particularly in the light of the known importance of dormitory overcrowding for the spread of meningococci from the pharynx.

The family investigated by Zintek² was one of a group in Denver, Colorado, selected for a weekly collection of throat washings and faeces because one or more members had been in close contact with a case of poliomyelitis. No virus was detected in specimens collected on July 11 from the parents, from two sons aged 9 and 8, and from a daughter aged 6. On July 15 the 8-year-old boy fell ill with an abortive attack of poliomyelitis; on July 19 the elder boy developed poliomyelitis, going on to paralysis; and on July 20 the girl showed symptoms of an abortive attack. Throat washings from the parents on July 20 yielded no virus, but specimens of their stools inoculated into rhesus monkeys produced paralysis with histological lesions typical of poliomyelitis. Positive results were also obtained with throat washings taken on the same day from the boy and girl who had abortive attacks and with a stool specimen from the boy. Tests of stools from these children and from the father were again positive on Aug. 9, but were negative in the case of the mother. The failure to demonstrate the virus in a paralytic case eight days before the onset of illness and in two abortive cases four and nine days, respectively, before the onset contrasts with other cases in which the virus has been found 19 days³ and 12 days⁴

before onset. Despite the fact that the three children had been direct daily contacts of two cases, the infection of all five members of the family in so short a period seemed to the author to indicate a simultaneous exposure to some extra-human factor in the environment or consumption of a common vehicle. A less probable explanation was that infection had been introduced by one of them and had then spread in the family.

More studies of this sort, although they demand much field and laboratory work, seem to offer the only hope of understanding why multiple cases of poliomyelitis in families are relatively rare, and why they occur within a few days of one another, being apparently parallel cases and not serial infections as is the case with infective hepatitis.

MENSTRUAL TOXIN

Among the abundance of superstition and folk-lore attached to the phenomenon of menstruation from pre-biblical times there has always been a popular belief that the menstrual function allowed a periodic discharge of some noxious substance which if retained could be harmful to the organism. This concept is not now approved, but Smith¹ and Smith² have recently summarized work which they have been carrying out over the last eight years on "menstrual toxin." They have demonstrated that the menstrual discharge contains an atypical euglobulin derived from the endometrium during the last stages of its regression. It is a tissue-damaging agent which acts apparently by virtue of its vasoconstrictive properties. It is also fibrinolytic, and immunological studies have identified it with "necrosin," a toxic factor found by Menkin³ in inflammatory pleural exudate in dogs. Moreover, the pseudoglobulin fractions of this exudate and of menstrual discharge will neutralize the effects of the toxic euglobulin fractions. Smith and Smith point out that the identification of a product of endometrial breakdown with a protein released by cellular injury may indicate that tissue katabolism from various causes may release such a toxin. This in turn suggests a common pathogenesis for such conditions as traumatic shock, the crush syndrome, the toxæmia following burns, and possibly also the toxæmias of pregnancy—particularly concealed accidental haemorrhage. The varying clinical pictures may be due to variations in the amount of toxin produced, and the duration and circumstances of its action.

The toxæmias of pregnancy are involved in this theory, because further research has revealed that there is present in the blood of menstruating women, of women in labour, and of women with pregnancy toxæmia a euglobulin fraction with fibrinolytic activity and a pseudoglobulin fraction with a counteraction. These properties are absent from the blood of women during normal pregnancy and in the intervals between periods. Smith and Smith suggest that in menstruation, labour, and toxæmia these substances result from tissue breakdown consequent on the withdrawal of hormonal support. It follows that there may be a relationship between the constitutional and local disturbances that sometimes accompany menstruation and the production of a menstrual toxin which causes a degree of vascular damage. This damage is said to be similar in character to that seen in the endometrium itself immediately before the onset of menstruation. Clinically, it has been observed that menstrual molimina are less marked in anovular cycles, when, according to Smith and Smith, the menstrual flow contains less toxin than in ovular cycles. Similarly, the state of

pre-menstrual tension may be ascribed to a prolonged absorption of the toxin from a secretory endometrium, and the spasm of primary dysmenorrhoea to an exaggerated local effect of the toxin.

Smith and Smith point out that the finding of a fibrinolysin and of a protective pseudoglobulin in the blood in pregnancy toxæmia serves as a reminder that menstruation and toxæmia present other similarities, such as a tendency to water retention, a withdrawal of oestrogen and progesterone, and clinical improvement when the uterus empties itself of its contents. They contend that menstrual toxin is the precipitating cause of toxæmia, and they have accordingly started clinical trials to determine the value of protective pseudoglobulin in the treatment of pre-eclampsia. Meanwhile they report four cases of spasmodic dysmenorrhoea successfully treated by injections of pseudoglobulin obtained from such human exudates as ascitic fluid. In addition to subjective relief, a progressive diminution of circulating fibrinolysin was demonstrated in three of the cases after the injections. If these findings are confirmed and the protective pseudoglobulin can be prepared in sufficient and concentrated amounts, not only the less important menstrual molimina may be prevented, but also more serious conditions such as menstrual migraine and epilepsy. Further reports on the progress of these clinical trials will be awaited with interest. Smith and Smith, however, are considering an even wider application of their work, realizing that in theory toxic protein katabolites may arise from damaged tissues anywhere in the body and that therefore treatment of the resultant clinical syndromes with protective pseudoglobulin may prove of value in a large number of conditions.

HEALTH OF THE PRISON POPULATION

The prison population is increasing. In 1944 the daily average number of people in prison was about 13,000; this figure has risen steadily until in July, 1947, it stood at 17,300. It is now higher than it has ever been since before the war of 1914-18. Among women the daily average has fallen and now stands at about 1,000. There has been a marked decrease in drunkenness, or at all events a marked diminution in the number of women sent to prison for that offence. On the other hand, the number of women sentenced for brothel-keeping and for cruelty to or neglect of children has risen steeply. The borstal population seems to have stabilized itself at about 3,200. Young males found guilty of indictable offences and sentenced have increased by 50% since the pre-war years, and young females by an even higher proportion.

The annual report of the Prison Commissioners¹ concerns 28 local prisons, 5 convict establishments, and 13 borstals. When the figures were compiled 11 prisoners were in for life (commuted death penalty), and 22 were serving terms of twenty years. Some prisons seem to be overcrowded. Thus at Wormwood Scrubs the number of cells available for ordinary prisoners is 974 and the daily average population 982; at Bedford 118 cells hold on the average 132 prisoners; at Norwich 137 cells contain 157 prisoners. The exclusion of accommodation for special classes of patients, such as those suffering from venereal diseases or from certain skin complaints, and those segregated for punishment, may go some way to explain the difference, but it does look as though the housing situation in the country generally is reflected in its gaols. During the last year under review, restraint had to be applied to 71 male and 15 female prisoners, and corporal punishment

was ordered in 16 cases, but in 5 was not confirmed by the Home Office. The net annual average cost of a prisoner is £140, and of a borstal inmate £176. Whether this takes into account any economic value of a prisoner's work is not clear. The chief employment in local and convict prisons remains the making of mailbags, but in borstals a larger number of males are engaged on agricultural and building work.

Deaths in prison during the year numbered 55, of which 19 were due to executions, and 2 were suicides. The daily average number of sick prisoners treated in hospital was 838, and out of hospital 1,306. The total number certified insane (apart from those found guilty but insane, or insane on arraignment) was 79. Increasing use is made of temporary release to civil hospitals for medical and especially for surgical treatment; 257 prisoners were so released during the year. At Wormwood Scrubs there is a surgical unit which deals with non-urgent surgical cases from London and provincial hospitals. Wormwood Scrubs has, too, a psychiatric unit with a 10-bed ward, and another unit has been developed at Wakefield to deal with cases arising in the North of England. At Holloway—the women's prison—a psychological unit has been formed which helps in the allocation of girls for appropriate borstal training.

Experience has shown that however well qualified as a psychiatrist a medical man may be when he joins the prison service it is some years before he becomes of full use. The criminal aspects of psychiatry can be learned only in prison. For example, cases of schizophrenia commonly seen in prison are not of the type most suitable for insulin therapy, though some cases requiring insulin treatment are transferred from prison to a London mental hospital. For such therapy the patient should be of good previous personality, and the symptoms should be of recent development. In the cases seen in prison as a rule the personality is poor and the symptoms have developed slowly. The need for a general all-round experience in the prison medical officer is emphasized. The amount of ordinary medical and surgical treatment required in prisons is quite considerable, and psychiatric work is not the major part of the prison medical officer's job.

The question of the psychopathic personality is receiving attention. Three main types are recognized in prison: the aggressive psychopath, the inadequate psychopath, and the ethical aberrant personality. The last-named might properly be certified as a moral defective; the difficulty is in proving that symptoms existed before the age of 18, which is necessary for certification under the Mental Deficiency Acts. Certification would provide for the segregation of a group of social misfits, and would afford facilities for rehabilitation treatment over a long period in special clinics.

The epileptic state appears in a very small proportion of prison cases, apparently in only about 0.4% of the average prison population. The treatment of epileptics in prison is said to present no great difficulty. Many of them respond well to the usual drugs, but there are difficulties about their disposal on release. Not all epileptics go to prison for a crime committed in the pre- or post-epileptic state, and their crime has often no connexion with their disease. A colony for epileptics who have a criminal record and need institutional treatment is suggested. During the year covered by the report a medical adviser was added to the staff of the Home Office, and Dr. J. C. W. Methven, while remaining a Prison Commissioner, was appointed to this post. He advises the Commissioners on medical policy and exercises general supervision over the medical service in prisons and borstals.

TO EVERY MEMBER OF THE MEDICAL PROFESSION

STATEMENT BY THE B.M.A. COUNCIL

its meeting on Jan. 21, the last before the plebiscite is held, the Council of the British Medical Association issued the following statement:

We are now on the eve of a decision of the profoundest importance to the public and to the medical profession. For the British Medical Association has been working for extension, improvement, and consolidation of the country's health services, publishing its constructive proposals in a series of reports. It is now confronted with an Act of Parliament directed to the establishment of a comprehensive health service embodying forms of organization which are in conflict with the principles of the profession. The conflict is based on the profession's conviction that the Act leads unmistakably towards a whole-time State medical service, and that such a service would be harmful to medicine. This conviction is strengthened by the knowledge that the Act of 1946 is in the hands of those who profess as their objective a whole-time salaried State medical service.

We have sought a number of changes, some of principle, some of detail. The answer has been a refusal to modify one word of the Act. The Council recognizes that some points in the profession's case make a stronger appeal to some members of the profession than to others. But it firmly believes that, viewed as a whole, the Act in its present form is in conflict with the best interests of the community and the profession.

After years of discussion the time has come for the profession to translate words into action. The issue is one not of money or compensation but of the intellectual freedom and integrity of a great profession. The Council of the Association will abide by the result of the plebiscite, as defined on the plebiscite form. It would be lacking in its duty, however, if it did not make abundantly clear to every member of the profession its carefully considered and determined view that the profession should not take service under the Act in its present form.

TO EVERY INSURANCE PRACTITIONER

STATEMENT BY THE INSURANCE ACTS COMMITTEE

The following statement was drawn up by the I.A.C. at its meeting on Jan. 15:

The Insurance Acts Committee, which represents every insurance practitioner in the country, owes it to its constituents to make abundantly plain exactly where it stands on the rare issue which now confronts insurance practitioners, as it does other members of the profession. Fully conscious of all the implications, the Committee condemns the National Health Service Act, 1946, in its present form as contrary to the best interests of the public and of medicine, and advises insurance practitioners firmly to reject it in the forthcoming plebiscite.

A Bibliography of Infantile Paralysis 1789-1944, which is edited by Dr. Morris Fishbein and published at Philadelphia by J. B. Lippincott (price £4 10s.), is a valuable publication already well known to students of poliomyelitis. It has been prepared under the direction of the National Foundation for Infantile Paralysis. The volume consists of a list of all medical references to the disease published since 1789, with a brief abstract of most of the papers and a carefully compiled index of both subjects and authors. Supplements to the list are issued once a month. The book is admirably produced and has already proved to be a most helpful work of reference to those interested in the disease.

THE N.H.S. ACT: SOME PRACTICAL QUESTIONS

THE COUNCIL'S ANSWERS

We print below some of the practical and personal questions which individual members of the profession have put to the Association at meetings and by letter, together with the answers given by the Council of the B.M.A.

General Practitioners

Q. (1).—*I am opposed to the Act and intend so to vote. What risk do I run of losing compensation if the fight is unsuccessful?*

A.—If a sufficient number of general practitioners stand out, the fight will not be unsuccessful. General practitioners will be advised not to enter the Service only if the number of them opposed to joining is sufficient to secure successful opposition. Only if 13,000 or more general practitioners agree to stay outside and continue so to agree will the Association advise all general practitioners to stay outside. As a result the Minister may postpone the appointed day. If he does not, he will be unable to provide a comprehensive service. Whatever final settlement follows, the Association will insist on a non-victimization clause covering, *inter alia*, capital values. If a sufficient number of all general practitioners stand firm, all will retain their capital value.

Q. (2).—*There may be practitioners who vote for staying outside but who subsequently join. Is this not a real danger?*

A.—The Association will keep itself informed of the practitioners who enter, or apply to enter, the Service before the appointed day. It will advise general practitioners to stay outside only if the number not signing is sufficient to ensure success.

Q. (3).—*I do not wish or intend to join the Service. I am doubtful of the views of my neighbour and competitor. If he joins, whatever the outcome, I shall lose in income. What assistance is available to me?*

A.—If the plebiscite returns justify the Association in advising general practitioners not to enter the Service, there will be taken steps to bind general practitioners in small groups one to another to sustain resistance. But this will not ensure that no one will lose income under any circumstances. Financial aid will be available to meet hardship incurred in carrying out the Association's advice, particularly hardship arising out of commitments entered into, such as interest on loans, insurance premiums, and school fees.

Q. (4).—*Assuming the necessary majority against undertaking service and that, despite the profession's opposition, the appointed day is adhered to, how will general medical services be provided for the people, bearing in mind that National Health Insurance will come to an end?*

A.—(1) There will be too few doctors inside the Service to enable the Government to provide the promised service. It will be for the Government to meet the criticisms of the people when—as they may believe—they will be paying for a service which is not there. Incidentally, only 10d. of the social security contribution will go towards health services.

(2) General practitioners will make their services available to the public on a fee-paying basis. Their position will be that they are willing to enter a suitable comprehensive service but they are unwilling to accept the Act in its present form. They will be receiving no money from the Government and they will look to their patients for payment for the services they render.

(3) Clearly, the Government cannot allow such a situation to continue.

Q. (5).—*I qualified two years ago. Although I dislike the Act I cannot help being attracted by the notion that a practice will be made available to me on application. Is this the position?*

A.—Not exactly. To-day practices pass from one practitioner to another by the process of introduction with or

without a preliminary assistantship. Under the Act this will not happen. You will make application to start a practice, or to succeed to a practice, in a particular area.

If your application to start a practice is granted you will in effect "squat" as you would to-day, the difference being that you will receive £300 a year.

If you succeed to a death vacancy, or to a vacancy arising from unforeseen retirement, it is probable that by the time your appointment is made and you take up practice in the area the income will be very much less than it was when the vacancy occurred.

If you are appointed to a partnership the situation is likely to be better, though it is fairly certain that partnerships as we know them will not continue under the new order.

Q. (6).—*Is opposition to the Act opposition to Parliament?*

A.—No. The Act specifically provides and the Minister has affirmed that the doctor is free to apply or not to apply to join the Service. The Minister has stated further:

"Every doctor will have to decide for himself when the proper time comes whether or not he should take part in the new Service, and the profession as a whole will be free to determine their views on the Service when they know what it is to be."

This is precisely what the profession is now proceeding to do.

Q. (7).—*I am in a partnership of three based on a partnership agreement entered into eleven years ago. Will the agreement continue to be operative after the appointed day?*

A.—The Minister says that all partnership agreements in all their clauses will continue to operate just as if there had been no Act. Our legal advisers say the Minister is wrong, so far as those clauses which provide for sale and purchase of goodwill are concerned, adding that such is the ambiguity that there should be amendment of the relative sections of the Act before the appointed day. In short, no one yet knows the answer, and the Minister is going to set up a legal committee to investigate.

Q. (8).—*Does the remuneration conform to the recommendations of the Spens Committee?*

A.—It is doubtful whether the remuneration proposed conforms to the Spens Report in the middle ranges of income and certain that it does not conform in the higher ranges. But the Minister's proposals for remuneration are irrelevant to the main issues. Whatever the form of service, the Association will insist that the recommendations of the Spens Committee, accepted by both the Government and the profession, are accurately translated into terms of remuneration.

Q. (9).—*I am hoping to retire shortly. If I join the Service in order to obtain compensation and retire, when is it likely I shall be paid my compensation?*

A.—Compensation cannot be paid to any practitioner until the regulations for the apportionment of the global sum have been devised and until every claim has been made and approved. Only then would it be possible to apportion the global sum among those entitled to share in it. Inevitably this will take a considerable time; it may be as long as two or three years.

Q. (10).—*Does a restrictive clause binding an assistant not to practise within a certain radius of his former principal for a certain time remain in force after the appointed day?*

A.—Yes.

Q. (11).—*Among the conditions governing the loan on my practice there is one which says that I shall not without consent take any action which would affect the security of the lender. Can I vote against accepting service?*

A.—Yes. A vote against accepting service does not mean repudiation from National Health Insurance. That comes to an end automatically on the appointed day under the National Health Service Act, 1946. It is most unlikely that any consent which a practitioner might have to obtain from the lender would be affected by the vote of action decided on by a majority of

Consultants and Specialists

Q. (12).—*I am a consultant on the staff of a voluntary hospital and also in private consulting practice. I am opposed to the Act. If the plebiscite returns justify opposition, what shall I be called upon to do?*

A.—You, like all consultants on the staffs of voluntary hospitals, will be advised to continue with your hospital work and to refrain from signing any contract proffered by a Regional or Teaching Hospital Board. It is very unlikely that permanent contracts will be proffered in the next 6 months, although interim contracts may be offered. The Specialist Spens Committee is not likely to report for 6 months; until it has reported and the Government has considered its report it will be impossible to offer consultants effective contracts.

Voluntary Hospital Medical Officers

(from Junior House-man to R.M.O. or Registrar)

Q. (13).—*What are the implications to me of voting against undertaking service under the Act in its present form?*

A.—You will be advised to continue with your work as no dispute were in operation, renewing appointments or taking new appointments in the hospital field if necessary. All that is asked of you is that you should not enter the field of conflict, that is, that you should not enter the Service as a general practitioner or as a consultant or specialist until the conflict is over.

Whole-time Local Authority Officers of all kinds, including Public Health and Hospital Officers, Consultants, and Residents

Q. (14).—*I am opposed to the Act. What action do I take?*

A.—You will be advised to continue with your work, even if this involves entering into new contracts with new employing bodies to which you are automatically transferred. You will be asked not to enter the field of general practice, or to enter into contracts as part-time consultants and specialists with regional and teaching hospital boards.

Q. (15).—*I am a whole-time officer of a mental hospital. Do I answer all three questions of the plebiscite? If the plebiscite returns justify opposition, what am I expected to do?*

A.—If you are of consultant status you will classify yourself as such and answer all three questions. If you are not of consultant status you will classify yourself as a whole-time local authority (special hospital) officer and answer question only. But whichever your classification you will not be asked to discontinue your present work or to refrain from entering into contract with the regional board to which you may automatically be transferred. All that is asked of you is that you should refrain from entering the field of conflict as a general practitioner or part-time consultant.

General

Q. (16).—*I am not a consultant or a general practitioner or a hospital officer. I am opposed to the Act. What action do I take?*

A.—You will express your opposition to the Act in answer to question A of the plebiscite. You will not be asked to reply to questions B or C. What will be asked of you is that you should not enter the field of conflict as a general practitioner or as a consultant.

Non-victimization Clause

Q. (17).—*Will the Association insist on a non-victimization clause in any final settlement?*

A.—Yes. In any final settlement the Association will insist on a non-victimization clause covering all sections of the profession.

THE DAY OF DECISION

A LAYMAN'S OPINION

BY

COLM BROGAN

Medical men and women naturally judge the present conflict principally on professional grounds. The present issue may be wider, and it may therefore be useful to look at it through the eyes of a layman, of a potential patient the present Act is designed to help. We have therefore invited Mr. Colm Brogan to state his views on the impact of the Act on the public.

By the eve of the poll which is to settle the future of the medical profession, some facts had become clear beyond argument. There is now no doctor left who does not realize that the present offer of the Minister of Health is an invitation to take the first and irrevocable step towards a full-time, full-salaried State medical service. It is now equally clear that an overwhelming majority of doctors are opposed to the scheme. However they vote, they have already exposed their minds. If they vote for the scheme they will have voted, under duress, against their judgment and professional conscience.

It is vital to their own interest and to the interest of the community at large that they should vote against the scheme in a majority so overwhelmingly large as to represent the true finding of their instinct and their judgment. Their own interests demand an emphatic rejection. If the scheme as proposed by the Minister is put into operation, independent practice will cease to be possible, except for a handful of doctors, within a measurable term of years. That is what the Minister foresees and what the Minister intends.

The destruction of private practice would have a damaging effect on the standing of all doctors, including those who are already in the public service. These have been known to complain of niggardly treatment and niggling interference, but whatever inconveniences they suffer from now are small compared with what is in store for them if private practice should disappear. Do doctors in public employment fully realize that all their professional standards, including the financial, are maintained by the outside pressure of independent practice? The "never-ending audacity of elected persons" is curbed, to some extent, by the fact that the employed doctor can walk out and set up for himself if the conditions of his employment should prove unbearably vexatious. The position of the teaching profession carries an instructive lesson for doctors. The standing of teachers under the State is in every respect inferior to the standing of doctors, for the simple reason that few teachers can walk out of public employment without walking out of their profession. As a result, teachers are subject to restrictions, indignities, and modes of interference which doctors have not yet learned to tolerate. But, once the area of private practice is reduced to insignificance, the hard lesson will begin. They will learn while they earn.

But the personal welfare of doctors is of public interest only in so far as the contentment of all important workers is socially desirable; and there is no room for an outsider to advise them on their own interest. The standard of medical service is a vital consideration for everyone, but here again doctors are better able than any layman to estimate the inevitable deterioration of standards under a State monopoly and to judge the full force of such a grimly monitory phrase as "lax certification." There can be few doctors who imagine that their professional integrity will be easily preserved when they must advise and prescribe with one eye on the patient and one on the state of the public funds.

No layman has anything useful to say on those aspects of the controversy which are specially understood by doctors, but there is a wider aspect which directly and vitally affects the whole public and on which it may not be impertinent for a layman to write. For a full generation we have watched a steady extension of State power. The necessities of war greatly assisted the development of the omniscient, omnipotent, and omniscient State, but the development has increased in rapidity since the end of the war, because it has the authority of a truly monstrous political philosophy.

That philosophy makes use of high-sounding phrases, "the will of the people," "the will of the majority," "the sovereignty of Parliament," but these phrases thinly cover an abyss of tyranny, for they mean that a man must surrender his private conscience at the command of a majority.

The liberties of Britain were not won by majority decision, or by accepting the sovereignty of Parliament over all persons and in all causes. Religious toleration was won by lonely men who sought exile or met their death rather than submit their conscience to the sovereignty of the State. The trade unions gathered their first strength by defying the sovereignty of Parliaments which sinned against natural justice by denying to working-men their right to combine. The Tolpuddle Martyrs were martyrs to State sovereignty. Liberty is won by the few, and is held by the many. Who did it become a rule of British life that the sense of right must abdicate and the cry for justice be silenced before the majesty of a majority decision?

It must be said that the philosophy of majority totalitarianism has some singular advocates. It is advocated by men who had a record of highly combative conscientious objection during the first Great War, and by a few who were equally careful of their conscience during the second. There is a Minister in the present Government who must still remember how he chose to appear before a conscientious objectors' tribunal, although he suffered from a disability which made it totally certain that he would not be called upon to serve. It was not enough for him that the sovereign will of the majority had exempted him from service: he insisted on formally rejecting the sovereignty of that will.

There are other Ministers of the Crown who still count it as virtue that they thwarted Parliament by putting an end to intervention in Russia. They achieved this end by strikes and the threat of strikes. One of them, who still likes to recall that campaign, has a soft spot in his heart for manly independence, which tempted him to say a good word for the Grimethorpe strikers. Admitting that they were rather awkwardly stubborn, he was yet pleased to see that the spirit of vigorous independence still flourished in the land. If the doctors show vigorous independence in the plebiscite, we shall wait to hear a chuckle of approval from the same Minister. We may have to wait some time.

It must be said that the Minister of Health has not formally claimed that the sovereign will of Parliament suppresses the private conscience of the doctor. Indeed, for a long time he was careful to assure the doctors that they were free to enter the service or stay out, as they chose. But, as the critical day drew near and the mind of the doctors was unmistakably shown, Mr. Bevan issued a reminder that Parliament was still sovereign, and his broad hint became an outright declaration in the mouths of his supporters. Indignant totalitarians positively bellowed their rage in the *Daily Herald* and the *Sunday Pictorial*. They cried "Havoc" and "Treason" because the doctors showed an inclination to disagree with Mr. Bevan, whose own career of docile conformity surely entitled him to a better response.

It would be interesting to know how the totalitarians square their principles with their practice, for they have gone very far at times in condoning affronts to Parliament. They have kept a silent tongue over strikes which were conducted in open defiance of a law which they themselves had renewed, and they are rather fond of talking about what the organized workers will or will not stand, without reference to Parliamentary sovereignty. The trade unionist may steal the horse, while the doctor may not look over the hedge. Is it possible that the sovereignty of Parliament is another name for the dictatorship of her proletariat?

In fact, the doctors have not so much as hinted at any defiance of the sovereignty of Parliament. If the sale of practices becomes illegal, they will not break the law. When hospitals are seized by the State, they will not strike against that seizure. If a minority of doctors choose to serve the State their colleagues will accept and respect that decision. All they claim is the right to choose an option which the same sovereign Parliament has allowed to them, a right which would still be theirs even if Parliament denied it. It is said that Louis XIV once ordered a Minister to do something which was against his conscience. When the Minister refused, Louis said, "But I, your

King, can command you." The Minister replied, "No. You can command me to do this, or resign. I resign." Louis accepted the justice of this answer, but he, after all, was only an absolute monarch.

The importance of the plebiscite to the general public is this—that it gives the first gleam of hope that we may all live to see liberty recapture lost ground. The advance of authoritarianism has been almost completely unchecked, for the resistance has been individualistic and unorganized. Now, for the first time, the authoritarians are meeting a well-armed enemy in prepared positions. If the doctors have the will to join issue, the battle is already won. If the majority is sufficiently emphatic, the Minister will not be merely defeated; he will be routed, and the doctors will not have to suffer even a temporary inconvenience. There will be a new Minister of Health and a new approach to the problem. It must be remembered that a politician's claim on the respect of his colleagues is largely dependent on his powers of persuasion, his skill in turning awkward corners. If Mr. Bevan's offer is overwhelmingly rejected, even those who regard the rejection with grief and rage will admit, and even insist, that the fault was largely Mr. Bevan's. That will be easier than admitting that the scheme is profoundly wrong. A more plausible politician will take over negotiations, knowing that his own reputation is dependent on success. The doctors have literally nothing to fear, so long as they are true to themselves and to each other.

What is likely to happen on the national scale has already been most instructively rehearsed on the local scale. Although the authoritarians have not lost a big engagement, they did suffer a check in one skirmish, and that, significantly enough, was a medical skirmish. The nurses and doctors of Willesden told the Council that they would seek other employment rather than accept the forcible baptism of trade union membership. Finding that the closed shop carried the uncomfortable corollary of a closed hospital, the Council climbed down as hastily as a small boy getting down from a forbidden wall. But that was not all. Prominent Ministers and trade unionists vied with each other in making clucking noises of disapproval at Willesden Council. Willesden had really gone too far: doctors and nurses must not be interfered with. There will be much clucking at Mr. Bevan if he loses the vote.

There was great public relief at the Willesden decision, a general feeling that an almost intolerable thing had at last met with a check. If the doctors of Britain stand as firm on the national issue, the whole social atmosphere will be lightened and cleansed.

It has fallen to the doctors to meet and break the authoritarian demand. They have not asked for this responsibility and they have not welcomed it, but the layman may well be thankful that it is the doctors who have been called upon to fight liberty's Battle of the Marne, because they have all the means of conclusive victory, if they have the will. Far more depends on this than the future of medical practice. The future of personal liberty is in the balance. The doctors can strike a blow that will not only free themselves but will give hope of freedom to us all.

That is why the plebiscite is a matter of the gravest national concern. Our liberties are still large, but they are contracting, and an evil idea is gaining dominance. Now is the time to reject and refute the idea. Doctors have not sought this fight, but they cannot now avoid it, and they have the decisive weapon in their hands. Let them strike home for all of us.

It may be that doctors feel the public has shown little sympathy and understanding, but they have one infallible means of enlisting sympathy and provoking interest—throw out the scheme. The public will conclude, and rightly conclude, that the doctors must have a solid case because they gave a solid vote. This vote will rouse a general and startled interest, and the force of private opinion against public policy will be clear.

It is true that a small number of doctors will vote for Mr. Bevan's conditions because they honestly believe that the Minister should be the master of the situation. There are fewer doctors now who are ready to do this than there were two years ago, but the vote is still a vote of respect because it is a vote of "Yes" from conviction. That

is respectable. Others may vote "Yes" because they fear the consequences of voting "No." They vote from calculation. That, at least, is understandable.

But to vote "Yes" in a spirit of meek submission to the common will is scarcely respectable and scarcely understandable. To submit your moral and professional judgment to a majority vote is to give away the command of your conscience and accept, in exchange, an insignificant holding in the rule of your own soul. Those who are tempted to this abdication might reflect on the verdict passed, one hundred years ago, by a Frenchman on his fellow countrymen. The average French citizen was then much exhilarated by his share in the irresistible authority of the sovereign mass. Looking in the mirror, said the critic, a Frenchman flatters himself that he sees one-twenty-seven-millionth of a tyrant. But he forgets that he sees all of a slave.

If the men and women of the British medical profession remember the rightness of their cause and the practical strength of their position their vote will shake the air like a sudden shot of cannon. Men will rediscover that they have no wish to be any part of a tyrant, and no need to be any part of a slave. For the first time the invasion of liberty will have been met by something better than compromise, concession, and pleading. But we can expect the first shot of national deliverance only if the answer is nearly unanimous and fully determined. There are few doctors who do not know in their hearts and minds what answer they must give to the demand that they accept State service and dependence. But the answer must be firm and it must be final. It is, No. Not now. Not ever.

MEDICAL PRACTICES COMMITTEE

In a letter to the Secretary of the Negotiating Committee from the Minister of Health the Minister has notified his intention shortly to set up the Medical Practices Committee under Section 34 of the National Health Service Act, 1946. We publish below this letter, a reply from the Secretary of the Negotiating Committee, and the subsequent correspondence.

Ministry of Health,
Whitehall, S.W.1.
Jan. 2, 1948.

SIR,

Medical Practices Committee

I am directed by the Minister of Health to state that a part of the preparatory work which must be carried out to make the National Health Service ready by July 5 next is proposed shortly to take steps to set up the Medical Practices Committee under Section 34 of the National Health Service Act, 1946. The Act provides that the Committee shall consist of a chairman who shall be a medical practitioner, and eight other members, of whom six shall be medical practitioners of these six medical practitioners, at least five shall be personally engaged in medical practice.

The chairman and members are to be appointed by the Minister after consultation with such organizations as he may recognize as representative of the medical profession, and the Minister would accordingly be glad to receive any views the Negotiating Committee may wish to express on the following proposals.

The Minister proposes that the normal period of office of members of the Committee should be three years, members being eligible for reappointment, but that the first chairman and two of the other eight original members should be appointed for a period ending on March 31, 1950, three of the remaining members retiring on March 31, 1951, and the rest on March 31, 1952.

It is anticipated that in the first instance the chairman and some, at least, of the members will probably need to give nearly full time to the work, but that the work is likely to diminish later on. It is therefore proposed that the remuneration of the chairman at the outset should be £2,000 a year, subject to review if and when the work diminishes, but that he should not be debarred from also undertaking private work if he wished. The other members would be remunerated at the rate

f seven guineas a day. Travelling expenses and subsistence allowance on the same rates as are payable in the Civil Service could be payable in addition.

Of the medical members the Minister considers that one at least might have experience in Wales.

As regards the two non-medical members, the Minister suggests that one might be a barrister or solicitor of experience and the other a non-professional member of an Executive Council.

The Minister would be glad to receive any suggestions from the Negotiating Committee as to the names of persons who might be included by him in his consideration of suitable membership for the Medical Practices Committee.

It will be helpful if any suggestions or observations which the Negotiating Committee may wish to make could reach the Minister as soon as possible, and in any case not later than Jan. 21, 1948.

I am, Sir, your obedient servant,
D. RUSSELL-SMITH.

B.M.A. House, W.C.1.
Jan. 10, 1948.

DEAR SIR, /

I refer to Miss Russell-Smith's letter of Jan. 2. Following its meeting with the Minister, the Negotiating Committee decided to refer the Minister's reply to its constituent bodies and not to meet until those replies were available. As the Minister is aware, steps are being taken to ascertain, by plebiscite and otherwise, the views of the profession as a whole on the issue of service or no service, and it would be improper for the Negotiating Committee to respond at this stage to the invitation to comment on the Minister's proposals for the Medical Practices Committee or to put forward the names of suitable practitioners for membership. Not until the profession has determined its attitude to the Service as a whole will it be possible for the Negotiating Committee to consider putting forward such observations and suggestions, its action then depending upon the character of the profession's decision on the larger issue.

Yours faithfully,
CHARLES HILL,
Secretary.

Ministry of Health,
Whitehall, S.W.1.
Jan. 16, 1948.

DEAR SIR,

The Minister asks me to refer to your letter of Jan. 10 and to say that he notes that the Negotiating Committee are unwilling to join him in the consultation which he has offered regarding the choice of medical members for the Medical Practices Committee. If, at any time before he has completed the constitution of this Committee in accordance with the Act, the Negotiating Committee wish to offer any suggestions he will, of course, still be happy to consider them.

Yours faithfully,
J. M. K. HAWTON.

B.M.A. House, W.C.1.
Jan. 23, 1948.

DEAR SIR,

I refer to Mr. Hawton's letter of Jan. 16 in which it is stated that the Minister "notes that the Negotiating Committee are unwilling to join him in the consultation which he has offered regarding the choice of medical members for the Medical Practices Committee." Mr. Hawton's reply and these words in particular suggest that the invitation to the Negotiating Committee to nominate medical members of the Medical Practices Committee was sent at a time when it was perfectly clear that the Negotiating Committee could not comply in order to relieve the Minister of the legal obligation placed on him by the Act to consult the medical profession.

The Minister and his advisers were fully aware that when the letter of Jan. 2 was sent, the profession was in process of deciding its attitude to the Service as a whole and that the Negotiating Committee could not possibly compromise itself and the profession by nominating medical members for a body the need for which is one of the subjects of dispute. Having received the only answer which could in the circumstances be

given, the Minister now accuses the Negotiating Committee of unwillingness to join him in consultation and to hint that he proposes to proceed to appoint the Committee without such consultation.

The matter—and the method employed—is of such importance that it is proposed to publish the correspondence.

Yours faithfully,
CHARLES HILL,
Secretary.

Ministry of Health,
Whitehall, S.W.1.
Jan. 26, 1948.

DEAR SIR,

The Minister asks me to refer to your letter of Jan. 23.

It is the Minister's clear responsibility to carry out the decisions of Parliament and to bring the National Health Service Act into operation. To do that in proper time requires the setting up, stage by stage, of the various administrative and other bodies for which the Act provides. The stage at which the Medical Practices Committee needs to be considered having arrived, the Minister offered the profession's Negotiating Committee the opportunity of consultation, as he would himself prefer—and has often made clear—to act throughout in the closest consultation with the profession. While he notes that the Negotiating Committee felt unable to join him in consultation in this instance, it remains his wish and intention to continue to offer the opportunity at all similar stages in the preparation of the new service.

The Minister has, of course, no objection whatever to your publishing this correspondence, including the present letter.

Yours faithfully,
J. M. K. HAWTON.

THERAPEUTIC SOCIAL CLUBS

AN ADVENTURE IN SOCIAL PSYCHIATRY

A meeting organized by the Institute of Social Psychiatry was held in London on Jan. 14 to further the idea of therapeutic social clubs for patients both in and out of mental hospitals.

Dr. E. B. Strauss, who presided, said that of the "big three" in medical psychology it was Adler who paid most attention to man's relation to his neighbour. Freud and Jung were more concerned with his internal harmony and integration. Psychotic patients were disoriented in time and space, but what was not so usually recognized was that any form of emotional or mental disturbance caused disorientation in a third dimension—that of the community. The therapeutic social club was one of several devices intended to counteract this. Among patients in mental hospitals, in addition to the disorder for which they were admitted, there tended to develop an "asylum psychosis," as a result of which they felt that they had sunk in the social scale and did not belong to the community.

Dr. J. Bierer, director of the Institute of Social Psychiatry, said that experience of therapeutic social clubs now extended over a period of nine years. He spoke in particular of the club started at Runwell Hospital in 1938-9. Many problems had to be faced in the establishment of such a club—how to combine freedom of action and self-government, including the mixing of the sexes, with existing regulations, traditions, and responsibilities. If patients were put in charge there was, of course, the risk of an aggressive patient taking possession of and misusing the club for the exploitation of his aggressive instincts. On the other hand, if a psychiatrist or nurse were in complete charge the patient would feel that he had no say in the matter at all. The best solution was to let the patients have charge of the club, the nursing and other staff attending by invitation, but to have honorary members, including the medical superintendent, the matron, and the psychiatrist.

In the club of which he spoke a few marriages of members had taken place and had been surprisingly successful. Two friendships had to be interfered with in order that they might not develop into a more serious alliance—one concerned an epileptic and the other a patient with multiple sclerosis—but in the majority of cases there was no reason to suppose that any harm would follow, either from the eugenic or the human point of view. Conditions in the club approximated more or

less to everyday life. The majority of patients behaved more naturally in the club, and this made it possible to use it for diagnostic purposes. A second club was established in the institution for chronic and deteriorated patients, and gave them some opportunity to exercise initiative.

One difficulty was that patients got so accustomed to active social life in the hospital that they missed it after discharge, and this led to the formation of extra-mural clubs. This idea underwent a large extension when they were confronted with the large number of asocial, solitary, and retiring people attending out-patient departments. In forming such extra-mural clubs it was important to avoid any stigma, and therefore the club premises were away from hospitals and the name of the club was non-indicative. In most of the clubs friends and relatives were also members; some of these were potential patients, and thus the club was of assistance in prophylaxis.

Dr. Donald Blair, deputy physician-superintendent at St. Bernard's Hospital, gave some practical directions on the starting, management, and financing of a club. The maximum number of members, he thought, should be between forty and fifty. It was important to have a nucleus of patients of reasonably high intelligence and initiative, and the regular attendance of the psychiatrist at club functions was of the utmost importance. These functions should include discussions, lectures, dances, and dramatic presentations. Therapeutic measures should be confined to talks to patients with proper encouragement and suggestions.

Other short addresses were given by Miss K. Thompson, social therapist at Runwell Hospital, Dr. Noel Harris, Dr. Doris Odlum, and Dr. Maxwell Jones, and much interest was shown in the discussion which followed.

Reports of Societies

MANAGEMENT OF UTERINE INERTIA

At a meeting of the Section of Obstetrics and Gynaecology of the Royal Society of Medicine on Jan. 16, with Mr. A. J. McNair presiding, the subject for discussion was the management of uterine inertia in the first stage of labour.

Mr. D. M. STERN said that uterine inertia might be said to occur when the contractions of the uterus during labour were shorter, less frequent, or weaker than normal. Normal labour might be assumed to last up to twenty-four hours, and prolonged labour was anything beyond that time. The first group of causes of uterine inertia in the first stage might be described as a badly fitting presenting part, including abnormalities of the foetus and the birth canal, and also, of course, placenta praevia. The second group of causes might be described as fear—not a surprising thing when women were educated to expect that labour would be painful. Less common causes included hormonal ones, of which little was known, excessive multiparity, drugs and poisons, accidental antepartum haemorrhage, and, of course, a full bladder or bowel. He did not agree that general debility was a cause; on the whole, debilitated patients had a rather more rapid labour than normal. Treatment was principally the correction of the abnormal presentation and reassurance of the patient.

In an analysis of 23,000 cases during the period 1936–46 labour was found to have lasted for more than 24 hours in 4.85, or 21%. Among these were a fair number of women who had previously had one or two confinements, but generally the proportion of primiparae was found to increase among the group which had the longest labours. There was little increase in duration with length of labour, and maternal mortality was not noticeably increased. The foetal mortality rate was estimated if the labour extended only over three days, but it was found to double if labour reached the fourth day, and to triple if it reached the fifth day. In the course of the analysis, 50 of the mothers who were admitted had lost their babies in their previous confinements, and in 28 cases the mothers had died, but among these 28 all the second attempts at delivery were successful, and in 15 the second attempt was prolonged and

Three Types of Primary Inertia

Prof. H. J. DREW SMYTHE described three main types of primary uterine inertia. The first was characterized by ineffectual pains from the beginning of labour, everything else being normal. Such pains might continue for three days, as the cervix did not dilate nor did the membranes rupture; relaxation or retraction of the uterine muscle was absent. The second was the clonic uterus, exemplified by the patient who from the beginning of labour had strong contractions, but in spite of these the cervix did not dilate and the membranes frequently ruptured early, with foetal and maternal distress. A posterior presentation, with which this delay in dilatation of the cervix was often associated, added to the difficulties. The form of primary inertia was found most often in the "male" type of patient. The third type of primary uterine inertia was associated with fear. Patients of this type from the very first pain shouted for the doctor to deliver them and became more and more hysterical, so that instead of relaxing they contracted against the uterus as much as possible. These cases were not common in hospital practice but were extremely common in private practice, and, he regretted to say, among doctors' wives.

In patients of the first of these types, if sedatives were given, the ineffectualness of the uterine contractions was prolonged. Sedatives should not be given during the day, but the patients should be ensured sleep at night, preferably with morphine. Rupture of the membranes in the first stage of labour was the danger with these patients. The thing to do was to get the patient on to full dilatation, which might take one, two, or more days, and when this was reached and the head was fairly down they should be delivered by forceps. Special care must be taken in the third stage of these labours, because then the same kind of inertia might be experienced. He never allowed the placenta to remain in the uterus for more than two hours. Definite shock was associated with longer retention of the placenta.

Patients of the second type, in whom the uterus went on contracting and the cervix failed to dilate, did require sedatives. The question whether there was foetal or maternal distress which demanded delivery of the patient depended entirely on how far the cervix was dilated. If it was not dilated up to half there were two choices—caesarean section or incisions of the cervix. Of the latter he had no experience. If the cervix was more than half dilated it responded well to some of these cases to further manual dilatation.

In the third type of patient in whom the inhibitory mechanism was an emotional one, namely, fear, treatment must start in the antenatal period. It was important that so far as possible the patient should be under the same doctor during the whole period of pregnancy and parturition. His condition was partly due to entering a strange environment and coming under different medical care when labour was imminent. With the anxious patient reliance must be placed during the first stage of labour on fairly strong sedatives. Often one was more or less compelled to use the forceps on these patients owing to pressure from their families. The alternative was to give them the old "twilight sleep," but this prolonged labour and might tip the balance against the child. Secondary uterine inertia during the first stage of labour was almost certainly due to disproportion, which demanded operative intervention.

Points in Treatment

Mr. J. V. O'SULLIVAN said that he took inertia to mean the prolongation of the first stage of labour over thirty hours. The classification might be into primary and secondary, primary where the cause of the weak pains was not known, and secondary in those cases in which the cause could be found. Everybody agreed that post-maturity and endocrine imbalance gave rise to inertia, and so did interference with the polarity of the uterus. He had never been able to understand how the uterus, which appeared to be one organ, could contract in the upper part and relax in the lower, and in fact he did not believe it; he believed that the upper portion simply contracted more strongly than the lower.

Sedation was necessary at some stage in all these cases. His practice was to use drugs as far as possible only by night, and indeed to avoid all sedative drugs for as long as was reasonably

possible. He reserved morphine for those cases in which there was clonic uterine contraction and those in which the inertia was due to fear. The difficulty with morphine was that once the patient had it she would not do without it. He found a high foetal mortality in cases in which morphine had been used. He had not much faith in uterine stimulants. He believed in 2 oz. (57 ml.) of castor oil, followed by an enema and a hot bath, as a suitable stimulant on the second day.

Sepsis was a danger, and for that reason he recommended a routine vaginal culture. On the third day he put the patients on prophylactic sulphonamide, and if necessary added penicillin. The important day was the third day. After 72 hours the risk of caesarean section became rapidly less serious. On the third day he always had an x-ray anteroposterior and lateral view taken. Where medical treatment failed surgical measures became necessary. In cases where the cervix was two or three fingers dilated and where pains were regular (very rare cases, perhaps 3 in every 1,000) he still cut the cervix at the 9 o'clock and 3 o'clock positions. Cases which required this were those where the head was deeply engaged, the membranes ruptured, and the cervix very thin. Caesarean section in his practice had only a very limited use. In conclusion Mr. O'Sullivan quoted figures from one hospital last year with 1,739 labours; there was inertia in 100, among which spontaneous delivery took place in 35, forceps delivery in 51, the cervix was cut in 7, and 3 caesarean sections were done. He quoted an old admonition which seemed specially applicable to inertia: "In all cases we seek to determine not what the woman can endure, but what she can accomplish."

Prevention of Inertia

Prof. W. C. W. NIXON said that in many obstetric clinics labour lasting longer than 48 hours was put into the category of uterine inertia. Whether such a statistical compilation was useful was open to doubt. Prof. Nixon showed some tables illustrating the incidence of uterine inertia among the cases at University College Hospital. Prolonged labour (over 48 hours) was recorded in 7.6% of the cases during the two years 1946-7. About three-fourths of the women delivered themselves. Was it possible to prevent uterine inertia? Although Mr. Stern had shown that it was not entirely a condition restricted to primiparae, yet on the whole it might be taken as such. Prophylaxis should start early in pregnancy and should be continued into the delivery period. Encouragement, sympathy, and the administration of the proper sedative at the proper time would do much to allay fear and to inhibit its effect on the dilatation of the cervix. Active movement in the early part of the first stage should be encouraged. Attention must be paid to fluid control and the condition of the patient. Among the established cases of uterine inertia the most anxiety was caused by those in which the contractions were feeble and the cervix remained stationary at two to three fingers' dilatation.

On the assumption that it was on the parasympathetic side that help was needed, in a recent case at University College Hospital where labour had been in progress for 52 hours, and the membranes had been ruptured for the same length of time, prostigmin was tried. Bundle contractions were slightly increased, though only temporarily, and the dilatation of the os remained the same, namely, three fingers. This patient weighed nearly 95 kg., and had put on nearly 18 kg. in the last six months of her pregnancy. There was so much distension of the distal colon that only a small area on the right side of the uterus could be palpated. Although the foetal heart could not be heard caesarean section was done and a live baby delivered. All that the prostigmin did was to reduce the blood pressure, the systolic from 172 to 128, the diastolic from 104 to 78 mm. Hg. The only complication in the puerperium was a urinary tract infection.

The haphazard use of pituitary extract was to be condemned, but there were cases of uterine inertia in which it could be given provided there was no disproportion, that the woman was not of excessive parity, and that there was no malpresentation. Prof. Nixon demonstrated an improved instrument, devised in Budapest, for measuring uterine tone. The instrument made it possible to determine in which cases pituitary could be given with safety. If the tracings of the uterine contractions showed the uterus to be in a state of hypertonus, then

obviously it was inadvisable to give pituitary extract. The reason why this drug had fallen into such disrepute was because cases had not been selected properly. When hypotonic inertia was shown it was quite safe to give the drug, and the effect of the first injection was to be seen in a few minutes.

In discussing surgical procedures Prof. Nixon said that when labour was allowed to be so protracted that there was excessive clonic distension with the drawing up of the bladder almost to the umbilicus he made it a rule to terminate the case by caesarean section. Much harm had resulted from the teaching that the delivery, if the membranes had been ruptured, must at all costs be by the vagina. Unnecessary vaginal mutilation, predisposing as it did to infection, had resulted from the adoption of this inflexible attitude in obstetric practice. He had never yet regretted doing a caesarean section for cases of protracted labour, but in some cases he wished he had not shown so much zeal for vaginal delivery.

General Discussion

Dr. ALECK W. BOURNE said that he entirely supported Prof. Nixon in what he had said about the use of pituitary extract. It should not be given in any circumstances in which there might be mechanical difficulty in labour. With regard to manual dilatation of the cervix, it was worth bearing in mind that there might be as the hours passed no apparent increase in size, but there was an increase in softness, and, for example, even though one had failed to dilate manually at 8 a.m., one might find six hours later that, while the cervix was no bigger, the fingers would open it up perfectly easily. If the head was fairly well down and the cervix was pressed over the head there was no place for caesarean section. Incision of the cervix would never enable it immediately to dilate because the constricting power of the cervix was in the ring.

Dr. GRANTLY DICK READ said that in his view there were three types of uterine inertia. The first was found in the women who went into apparently definite labour and stayed there, starting with weak regular contractions, prolonged into severe and painful contractions, coming on a fortnight or three weeks before the baby was expected to be born. These patients got a tender and sensitive uterus. The contractions caused distress to the mother, not to the baby, in his experience. These cases were not true labour at all. When, later on, normal labour did begin the women knew the difference at once. They would say, "Now that is different; now I am in labour." In nearly every such case, on investigation, an anxiety state was disclosed. The second type included those whose labour lasted from 36 to 50 hours, with weak contractions, though not distressing to patients who had been told how to conduct their labours, nor causing distress to the child. It would be found in most of these cases that there was some psychological factor working towards neuromuscular imbalance. The third type had a good labour until about three fingers dilatation of the cervix, and then there was an emotional storm, many women giving way entirely to the emotional state.

Treatment was to give fluids, to give rest, but, above all, to give confidence. There should be no hurry, no disturbance, but an atmosphere of complete calm. Sleep must be induced, particularly at night; exercise during the day was better than lying in bed. One of the greatest evils in obstetrics was the impatient attendant. If after three days there was no evidence of labour he suggested that the mind of the patient be investigated as well as the pelvic mechanism.

Mr. JOHN HOWKINS related particulars of a private case in which epidural anaesthesia was employed. This was a patient whom he had "conditioned according to the best Grantly Dick Read technique," and she went into a good labour. Then epidural anaesthesia was given, the anaesthetist, against his advice, giving her 45 ml. This led to an intractable primary uterine inertia—or really a secondary inertia, for the prime cause was the anaesthesia. Eventually she was delivered by the vaginal route. Unlike Mr. O'Sullivan, he was convinced that the uterus was two muscles differently innervated, one presumably by the parasympathetic, and the other by the sympathetic.

Two of the opening speakers made brief replies.

Correspondence

Censorship

SIR.—The letters from Mr. J. Johnston Abraham (Dec. 27, 1947, p. 1053) and from Mr. R. F. West (Jan. 10, p. 69) draw attention to what is one of the great dangers in any State medical service: the fettering of free expression of opinion. The strength of medical practice in Britain has been the doctor-patient relationship. The patient knows his doctor as a man. He knows his wife, his children, his dog, his car, his way of life. He chooses him when he is ill because he trusts him as a man. He comes to him for his opinion and his help, believing that the opinion will be honestly given and the help the best he can provide. Were he to think, or even to suspect, that he was being handed out the stock doctrines of authority, or given the treatment enjoined in the latest circular from headquarters, he would lose this belief.

We have passed through a long period in which truth has been at a discount and honesty an unpopular virtue. Speakers and writers have uttered advisedly rather than freely. They have said what they were told to say, what they felt they ought to say, what they were afraid they might-cause-alarm-and-despondency-and-let-the-side-down by not saying, rather than what they passionately desired to say. We want truth and freedom to walk among us again. How many enjoy them to-day?

Men who enlist in a service lose the right to publish as they like. Those who work for the Medical Research Council must submit to a benevolent guidance. Servants of Government departments must express opinions that fit the policy of the moment. Experts who are asked to report must suppress their report if its findings fail to confirm the views of the Minister who asked for it. Ration analyses, health statistics, nutrition surveys, all fall obediently into line with the propaganda programme. Are potatoes plentiful?—they are magnificent food. Are they scarce?—they are starchy rubbish.

Medicine can advance only while the right to speak and publish freely is open to all medical men; while the small man working without a research grant or the help of a well-equipped laboratory can put forward his humble thesis with as much right to be heard as the hall-marked and salaried professor; while new ideas gain ground because they are backed by facts and not because they are backed by authority, and old ones disappear because they are disproved and replaced by something better, and not because they are suppressed.

Magna est veritas et praevaleret. Will it after the appointed day?—I am, etc.

London, W.1.

HENEAGE OGILVIE.

SIR.—My attention has been drawn to the letters of Mr. Johnston Abraham (Dec. 27, 1947, p. 1053), and Mr. R. F. West (Jan. 10, p. 69). Their insistence that the medical press must at all times and at all costs be kept free from official interference is one which appeals to my heart and one which specially concerns tropical medicine. To this subject workers of all nations have contributed, and for this development unfettered and unbiased criticism has been most necessary. On many occasions when official views have been promulgated—as, for instance, in the manner of transmission of yellow fever, malaria, cholera, or plague—they have proved erroneous. Therefore I cannot imagine any Government in this country being so foolishly as to press for a muzzling of medical publications, and if there is any tendency to do so we must fight.—I am, etc.,

London, W.1.

PHILIP MANSON-BAHR.

SIR.—Among those called upon to vote in the plebiscite are medical men who devote most or all of their time to research. One point which has been discussed in your correspondence of late (Mr. J. Johnston Abraham, Dec. 27, 1947, p. 1053; Mr. R. F. West, Jan. 10, p. 69) concerns them directly and is the freedom of publication. In the absence of freedom of publication, which does not seem to have been given, the freedom of research will be endangered. The Health Act.

Other points at issue between the Minister and the profession may not concern the research worker so directly; nevertheless the freedom and the conditions conducive to good work which he enjoys depend upon the maintenance of the freedom of the profession as a whole. If we as research workers feel that the refusal of the Minister to grant the desired concessions do threaten that freedom, then it is our duty to place ourselves alongside our colleagues who are in practice and return a decided "No."—I am, etc.,

London, W.C.1.

J. A. FRASER ROBERTS.

SIR.—Mr. J. Johnston Abraham's letter (Dec. 27, 1947, p. 1053) raised questions of such fundamental importance to medical education that I expected his challenging communication would be followed by correspondence from those better qualified than myself to express their views. The absence of this, combined with a belief that Mr. Johnston Abraham sounded a note that, if not heeded by the profession, may lose us one of our birthrights, causes me to call attention to the fact that, except in the case of medical literature issued by or on behalf of, the Ministry, the Ministry of Health, while sponsoring a complete health service for the nation, has not established a single priority for medical literature in the important matters of delivery of paper from the mills, printing, and bookbinding. Consequently medical students' textbooks take their turn for paper, printing, and binding with manuals of greyhound racing and "How to Play Poker."

As yet, none of the priority Government publications designed for the use of medical students, but one must presume that in due course trainees for a Civil Service will be issued with official handbooks. While I am open to conviction, after a critical examination of Government medical publications, have formed the opinion that the Ministry of Health's official student textbooks, if and when they are available, are not likely to appeal to medical students as those compiled and produced by private enterprise. In my view something is lacking in the official publications; they fail to reveal the spirit of an unfettered Aesculapius striving to pass on the torch of knowledge for the good of mankind and the advancement of the profession. Undoubtedly it is the censorship which Mr. Johnston Abraham deprecates that tends to stultify these and other communications that emanate from the pens of medical writers who must obtain official permission to write.—I am, etc.,

London, W.1.

HAMILTON BAILEY.

SIR.—I entirely agree with the remarks of Mr. R. F. West (Jan. 10, p. 69).

While serving during the war, as M.O. to an Ordnance Depot, I had occasion to write to *B.M.J.* a report of what I considered to be an unusual case of idiosyncrasy to strychnine. I soon discovered that it was not as easy as all that. It had to go through the usual channels. First the C.O. (R.A.O.) had to peruse the report, and on his profound knowledge of medicine, acquired as a business executive, allowed it to go through to the A.D.M.S. He in his turn allowed it to go through to the D.D.M.S., who after a considerable delay passed the document as fit for publication.

I take it that this procedure was necessary to protect the Editor of *B.M.J.*, who must have been considered to be incapable of deciding whether this sinister report would have been of use to the enemy.—I am, etc.,

London, E.9.

P. R. SAVILL.

A Decisive No

SIR.—To one who has followed this controversy as anxiously and closely as I have done, ending up with the masterly analysis of the situation by our Secretary on Dec. 31 and attendance at the gallery at the S.R.M., there will be no difficulty in answering the plebiscite. But I am well aware that there are many doctors who have no time, or no inclination, for study of complicated issues which have been raised, especially by the astute appeal made by the Minister. I therefore offer what I think is a legitimate simplification of the problem which will face all recipients of the plebiscite.

In a body so large as ours it is impossible to attain unanimity on any point, but on one point we have approached it so nearly as makes no matter. To those who are doctors first and

politicians after, a whole-time salaried service is hateful. Well, look at the following facts: (1) The policy of the Labour Party is to have such a service. It has never been disguised. But Mr. Bevan as a strategist realizes that sapping is his policy and not a frontal attack. (2) He therefore enacts that any doctor entering the Service must (a) sell his practice to the State, and (b) accept a basic salary, the amount of which can be varied at the will of the Minister. The rest is easy. The "ripening" process is entirely in his hands. It seems to me to follow logically that if we are still against a whole-time salaried service the answer is a decisive "No." But for the sake of our credit as consistent people let it be decisive. If it is not, then for heaven's sake let us stop talking of our "principles."

I am still sufficient of an optimist, even in these fantastic days, to believe that the answer will show that "surely in vain the net is spread in the sight of any bird"—a remark made in the book of Job, who was as patient under provocation as our Negotiating Committee seems to have been.—I am, etc.,

London, S.W.7.

ALFRED COX.

Twelve Reasons for "No"

SIR.—There are at least twelve reasons why we should vote against entering into contracts under the National Health Service in its present form.

1. If we do not look after our own interests no one else will do so for us.
2. Those who may be inclined to approve the Act on the grounds that, in their opinion, the terms offered are acceptable should reflect how much better those terms will become if we reject the Minister's offer now with a united voice and subsequently negotiate our own terms.
3. If the general practitioners allow their goodwill to be filched from them the last vestige of medical independence will go.
4. If they once accept even the theory of basic salary the same thing is likely to occur.
5. The remuneration proposed for general practitioners is arbitrarily determined by Ministerial regulation, and once we enter such a service our incomes are entirely within the Minister's power.
6. The consultants and specialists do not yet know what their remuneration is likely to be.
7. At present a Public Health Officer can seek employment under another local authority if he is not satisfied with his position. In the National Health Service terms and conditions of service will be uniform throughout the country, so there will be no advantage in moving.
8. It will undoubtedly redound to the benefit of the public if the Act is amended to ensure professional independence and freedom.
9. I am quite sure the public can rely on getting a square deal from a free profession. I am equally sure the profession cannot rely on getting a square deal from a politician.
10. Not a single one of the principles enunciated by the Negotiating Committee has been conceded by the Minister.
11. The Minister's reply to the Negotiating Committee is full of misleading statements and leaves the question of partnership agreements in a complete legal fog.
12. The Minister's reply states the Act will be amended as it is found wanting. It has already been found wanting in respect of partnership agreements and yet remains unamended.—I am, etc.,

Harrow

J. B. WRATHALL ROWE.

No—and Why

SIR.—On Dec. 15 last I was informed in a letter from the local insurance committee that I may use only drugs in their list, or appendix, when treating insured patients. I may not therefore use, for instance, penicillin tulle gras. On Jan. 15 I received from the regional petroleum office exactly half of the amount of petrol for which I had applied, although the signed log that I enclosed with my application clearly showed the amount of petrol that I use each month. Just two examples of bureaucracy, and just two more reasons why I shall vote "No."—I am, etc.,

Kirkbymoorside.

RICHARD N. THEAKSTON.

No

SIR.—I had not intended to add to the many letters *re* the Health Service Act, but I have been stung into so doing by a happening to-day. Obviously the only line of action surely to prevent the surrender of Medicine to Socialist doctrine is to say "No, take it away," to the Act as it stands. What will happen after saying "No" one cannot say, and I was in some doubt as to whether the B.M.A. had thought of all eventualities. After listening to Dr. Hill at the local B.M.A. meeting I was in doubt no longer, and could see clearly how "No" could be sustained, how it would gain its end, and both the personal and general likely course of events. The case for "No" is unassailable compared with "Yes." It is dangerous even to think "Yes," for this leads to confusion of thought and inability to see that "No" can, and must, be sustained whatever happens. Yet immediately after the meeting I was flabbergasted to find an intelligent fellow doctor (not a G.P.) toying with the "Yes" attitude from personal considerations, and apparently unable to see how a united "No" could be consistent with continuance of his employment, etc. I assessed him as a nitwit on this, told him so, and tried to explain what Dr. Hill had just explained with complete clarity! Are there many nitwits?—I am, etc.,

Birkenhead.

A. M. FRASER.

Medical Students Say No

SIR.—I am amazed how little consideration has been given to the opinions of to-morrow's doctors. We medical students must stand by and watch others decide our future. We place all our hope in the good sense of those who are to vote in a few days' time. Let them remember that it is not merely their own private interests which are at stake, but the freedom of thousands of would-be doctors who have no say in the matter at all. If doctors accept the State Medical Service as it stands, with its many good points but several entirely unacceptable ones, they will condemn us to a life of State service which we had not bargained for when we took up medicine. If they do but stand firm, they can insist on a form of service which they would not be ashamed to hand on to us.—I am, etc.,

Cambridge.

PETER LYNE.

SIR.—May we—medical students—take up some of the valuable space in your *Journal*? On reading some of the letters printed in your correspondence columns one feels that their authors are chiefly afraid of the attitude of the young newly qualified doctors towards the National Health Service Act. We can only say that from our small experience of our fellow students, including many who have qualified during the last eighteen months or so, we do not believe that the majority of the younger members of the profession are so attracted by the present form of the Act as your correspondents fear.

Dr. Dan E. Davies, in his letter in your issue of Jan. 10 (p. 70), scorns the stated first principle for which the profession stands, or rather he refutes its sincerity. He declares that it really ought to read, "The medical profession in its own interest is opposed to," etc. He declares that our interests are purely selfish in opposing the Act. But how does this agree with the statements made by the Minister and all those who support the Act, when they say that in fact the Act is a good thing for the doctors as they will be financially better off and their "working conditions" will be much better? If our interests are selfish and the Act is to our benefit, why then do we oppose it?

As has been pointed out in your columns hitherto, the Lord Chancellor said, during the third reading of the Bill in the House of Lords, that the success of all their Socialist schemes—particularly their National Insurance scheme—depended upon satisfactory control of certification. Apparently they do not trust doctors to be honest in certification. We are selfish! We cannot be trusted! Altogether we're a pretty roguish lot! Let us for a moment agree with these people in their estimation of doctors, and see how this unmoral profession is going to fit into their National Service. There can be no doubt that the system of remuneration, with a basic salary proposed by the Minister, is but a step towards a full-time, wholly salaried service. This has been admitted by the Minister and others,

and announced in the official Socialist programme. And when this is so, when our income does not depend upon the numbers and satisfaction of our patients, we could not hope to gain anything by taking the extra care which differentiates the treatment given by a good doctor and that given by an indifferent doctor. Why should we, then, who have no real interest in our patients, give ourselves coronary thromboses by working a bit too hard? True, the State could sack the bad doctor who really wasn't doing his job, but what would it do with the whole host of indifferent doctors who would certainly not make the Service such a wonderful thing as the Minister apparently would wish? (Indeed, the excellence of the new Service is his only interest!) If the doctors are such a shocking lot, would it not be better to ensure their good work by giving them the inducement of capitation fees rather than a fixed salary? This would be the logical course for the Minister to take.

If the members of the medical profession are as the Lord Chancellor and others of the Socialist Party and Dr. Davies seem to believe, reactionary, Conservative, true-blue, worthless money-grubbers, then heaven help the patients under the form of Health Service at present envisaged in the Act!

Perhaps we may be young and innocent, and do not know the ways of the big bad world; but, though we do not believe that doctors are all saints any more than any other section of the community, we do believe that by far the majority of the medical profession are sincere in their concern for the welfare of their patients and in their desire for a good and comprehensive Health Service available to all. And we do believe (as we know do many of our fellow students—especially after a closer study of the Act and its implications and the Minister's type of negotiations during the last twelve to eighteen months) that the Act in its present form will *not* provide the improved Health Service that we wish to see in this country; and that the clear duty of every medical practitioner, in the name of everything that the medical profession holds sacred, is to refuse to have anything to do with the National Health Service Act in its present form.—We are, etc.,

PETER J. STEVENS.

Treasury Control

SIR.—As it is clear that many doctors, including apparently all those belonging to the Medical Practitioners' Union, have not yet read or digested the new Health Service Act, may I repeat the gist of some remarks I tried to make at the Special Representative Meeting?

The trouble with this Health Act is that it ties up medicine with financial insurance benefits, and this makes it a gigantic financial gamble, especially as sickness absence, in spite of the five-day week, which has reduced it, is still much higher than the Government estimates allow for. This being so, the last word is not, as commonly thought, with the Minister but with the Treasury, for Section 75 (3) of the Act clearly states: "Any power conferred on the Minister by this Act to make regulations shall, if the Treasury so direct, not be exercisable except in conjunction with the Treasury." We all know that it is the regulations even more than the framework of the Act that will decide what sort of service it is to be, and this is the clearest possible warning that Treasury control will be the dominating factor, as indeed we have most of us known it will be if the funds are to remain solvent. When, therefore, the Minister writes that the doctor "is left to look after his patients in his own way and to the best of his clinical ability. He is not 'under orders,'" and again, "There is no reason whatever why . . . the professional independence of the doctor should be affected by a switch-over from private fees to public funds," he is writing a demonstrable untruth, for even if Mr. Bevan should wish it he has no power to enforce it.

When the present spendthrift policy is changed, as it will have to be if the country is to survive, it is clear that the strongest possible pressure will be exerted on doctors to cut down present expenditure and individual judgment. Medicine will be a State business and the State will touch minds and souls as well as bodies, and the Act makes Treasury control the final arbiter.

The choice will be "submit, or change your job." How clinical freedom is to be maintained in a State health service is a difficult question, but this Act provides that the question should never arise. Treasury control—i.e., financial considerations—will settle the matter, and there is no appeal.

I also drew attention to Section 43, which gives the Minister power to do or dispense with practically anything in areas where he considers the services inadequate. This is Mr. Bevan's provision to break any "doctors' strike," being sure that, whatever happens, the doctors will not let their patients suffer medically. Section 43 states: "If the Minister is satisfied . . . as respects any area . . . that for any . . . reason any considerable number of persons in any such area . . . are not receiving satisfactory services under the arrangements in force under this Part of this Act, he may authorize the Executive Council to make such other arrangements as he may approve, or may himself make other arrangements and may dispense with any of the requirements or regulations made under this Part of this Act so far as appears to him to be necessary to meet exceptional circumstances and enable such arrangements to be made." This provision goes far beyond the Trades Disputes Act and should make any trade unionist blush with shame. The two sections I have quoted should also frighten patients as well as doctors who might be tempted to accept the Minister's blandishments at face value. Together they make this so-called social security measure one of the most retrograde pieces of legislation passed for a century. They are far more fundamental for medical practice than any of the details discussed by the Negotiating Committee, and amendments to secure their repeal or to introduce proper safeguards should most certainly be introduced before doctors think of accepting service under the Act.

A Minister who with Hitlerian cunning and honeyed word inserted such a dagger blow at professional and personal freedom should be disowned by any Government that claims to represent the people. In their opposition to this Act the doctors are not fighting to exploit the patients but to protect them, and with Treasury control they will need some protecting.—I am etc.,

Winsford, Cheshire.

W. N. LEAK.

The Fight

SIR.—We believe we represent many of the junior hospital doctors. We understand that those serving whole-time appointments at voluntary hospitals will be asked to vote with the consultants and general practitioners in implementing their "No" votes (if so they be) by an undertaking not to accept service under the Act as it stands. This group, which comprise registrars (including those with ex-Service grants) and resident forms a considerable number, and their decision generally may well influence considerably the extent of the majority against the Service. For this reason we urgently request information on the following points, as we believe it may help to clarify the issue for many in our position.

In the event of a majority of "Noes" from consultant G.P.s (including at least 13,000 of the latter), and resident those of us who have pledged our support will be asked to refuse to accept service.

(1) Will this be binding if our particular group (the residents) is in a minority, even though there is an overall majority?

(2) Though we are all to continue our medical work we may find this difficult for several reasons. We shall be working in hospital owned by the Minister and we shall be the only group of doctors with no possible source of income (except possibly for a small payment from the fighting fund). It is unlikely that the Minister will pay us unless we are prepared to join the Service, and he will not allow us the freedom of a token strike. In spite of current opinion to the contrary, he may well offer us terms and conditions of service on July 5, either temporary or permanent. If he cannot start the general scheme, he may well attempt to save face by starting the hospital service. Either we resign our jobs and starve, and the patients in hospital will be left to nature and the nursing staff (admittedly this is quite adequate in the majority of cases), or a sufficient number of us stay, who can staff the hospitals while the rest remain unemployed and fulfilling no useful opposition to the Act. It is useless for us to make local agreements because the

hospitals in all areas must carry on. Which of these alternatives shall we be asked by the B.M.A. to pursue?

(3) Those whose appointments come to an end in mid-summer will be automatically debarred from applying for any other hospital appointment in the country. This will apply to many residents whose appointments are limited to six months.

(4) What will be the effect on those at present working in teaching hospitals? They will be to some extent autonomous. Will this autonomy extend to allowing continuation of work (with or without pay) to those who do not sign on the Minister's dotted line?

Though, unlike the G.P.s, we have no capital at stake and therefore less to lose, we find that we are in a peculiar position, and we should be grateful for a more informative statement on the practical measures before signing the second and third questions in the plebiscite. At present many of us feel that this will be like signing a blank cheque to the B.M.A. (admittedly the alternative will be one to the Minister). We should be grateful if you, Sir, could provide this information.

We are opposed to the principles of the Act and we should like to do all in our power to resist it, but some of us have families to support, which we find almost impossible to do at the moment on very restricted incomes. We also think that an assurance that the B.M.A. (when they are in a position to state their terms) will press for better pay for us will give greater confidence to many of our friends. There are many who just cannot survive indefinitely on present salaries, and they feel that in the past insufficient support has been given them. All we desire is that many valuable votes to enhance the cause of freedom shall not be lost through want of clarity.—We are, etc.,

F. J. FLINT.
R. S. WEETCH.
A. J. BAILEY.
E. A. BROOMHEAD.
R. W. TEMPLE.

Sheffield.

* The Secretary of the B.M.A. comments: If the situation described in this letter arises, voluntary hospital medical officers will be advised to continue with their work as if no dispute were in operation, renewing appointments or taking new appointments in the hospital field if necessary. They will simply be asked not to enter the field of conflict—that is, that they should not enter the Service as a general practitioner or as a consultant or specialist until the conflict is over.—ED., B.M.J.

A Sufficiency of State Hospitals?

SIR,—As a physician who has served a municipal hospital for a number of years I hope I may be forgiven if I insert a few platitudinous observations. There has been some attempt in the past to represent the municipal doctor as an apathetic creature tied up in red tape and complacent in these curious bonds. In point of fact many of us have long been striving actively to meet demands which will be increased when the National Health Service comes into being and so cannot but foresee the increasing difficulties which will then be encountered.

These difficulties, met even in a live, supple, and efficient organization, include: (1) Insufficient beds to meet all the demands made throughout the year for the treatment of seriously ill patients. (2) The housing in hospital beds of infirm and homeless, but not sick, old persons, with consequent increase of difficulty. (3) The use of a number of wards, quite inadequate for the district, for cases of pulmonary tuberculosis who would be more conveniently treated elsewhere. (4) An insufficient number of nurses and orderlies to keep all the hospital wards open, further increasing difficulty. (5) An insufficient number of domestic staff and cleaners, which further aggravates difficulty.

When I consider these shortages of hospitals, hospital personnel, sanatoria, and of homes for the aged I do not forget that they probably occur much less severely in this progressive and wealthy county than in many other places. I do not inquire what possible shortcomings of a similar type there may be in the organization of the service outside the hospitals, but I hope that in these days of national poverty the general public is

not being led to expect something expensive and valuable which will neither be in existence this July nor for a long time afterwards.

We all look eagerly forward to the completion of a full hospital service throughout the length and breadth of the land, but can we now be assured that we shall soon see the end of the building difficulties which have so long balked those who would otherwise have built more hospitals and homes? Can we also be sure that there are available sufficient and suitable recruits for the nursing and domestic staffs just waiting to be attracted into the service by the ideal conditions of employment in State hospitals? But if both the "bricks and mortar" and the staffs are not assured, then surely we are contemplating a premature start of the scheme, and it is, at present, unjust to offer it to the public as a National Health Service.—I am, etc.,

Edgware, Middlesex.

G. H. JENNINGS.

Payment of Hospital Staff

SIR,—It is somewhat disingenuous for the Dean of University College Hospital Medical School to suggest (Jan. 10, p. 71) that the acceptance of salaries at this moment (part-time or not) by the honorary medical staff of his hospital, post-dated to January, 1947, has nothing to do with the imminence of a State medical service. At the meeting of the Marylebone Division I did not criticize them for so doing: I merely gave that hospital, among others, as an example of what was happening, and asked whether the B.M.A. (several leading members of Council were present) advised that this example should be followed by other hospital staffs. Nobody answered my question, but I cannot help thinking that if the honorary staffs of our leading hospitals had refused to contemplate accepting part-time salaries at this juncture it would have set a good example and helped to keep our profession united.—I am, etc.,

London, W.1.

R. SCOTT STEVENSON.

Unity of Profession

SIR,—The Minister's reaction to a plebiscite majority against accepting service will furnish a useful yardstick of his sincerity towards the general public. He states that he is actuated in the ultimate resort solely by his concern as responsible Minister of the Crown in the welfare of the men, women, and children whose care he undertakes (through the profession) and who are wholly dependent on that care. If his concern is sincere then by no stretch of his political imagination could he envisage an efficient service manned by resentful personnel forced by circumstances, chiefly financial, to become unwilling participants. Greater men than Aneurin Bevan have attempted and failed to enslave free peoples, and I am convinced that this would-be dictator will fail to enslave the profession.

The issue now confronting each individual is whether he wants to decline or accept participation in a whole-time State salaried service, whether he is prepared to stand by or reject the well-considered and matured advice of the Council of the B.M.A. If a majority of the profession shows at the plebiscite that it wishes to participate, we, the antagonists, will throw in our lot with it and hope for the best, but should the state of affairs be reversed I would appeal to the minority to stand by the majority vote. Such unity is absolutely essential. I would also exhort those contemplating accepting service, or those who may be wavering, to think carefully on the main issue once again. Loyalty to the majority vote and to the Council's advice should be an honourable duty. Self-interest, especially thoughts of financial gain, must be eliminated. The retention of freedom for patient and doctor ought to be the dominant consideration.—I am, etc.,

Burbage, Leics.

CHARLES O'DONOVAN.

Strong Position

SIR,—In your leading article of Jan. 10 (p. 53) occur the words: "The medical profession is in a strong position and should be more conscious of that fact." Personally, I would state the case more emphatically and say our position is not only strong but can become unassailable if we choose to make it so. United, we are all-powerful. We have only to decide if we are justified in applying such power. Some might hesitate to use it arbitrarily, but I think the vast majority must

feel so sure of the justice of our case—which is nothing less than safeguarding our profession from utter serfdom and degradation—that the end justifies the means. Standing together, we have absolute power and the Minister is helpless. On the other hand, if we work the Act we hand this power to the Minister on a platter and deliver ourselves into bondage. Already the Minister has attempted to crack the whip while we in fact still hold it. What if we allow him to obtain a firm grip? Almost unanimously we have agreed upon certain principles regarded as absolutely essential for the future welfare of both patient and profession. These principles are *not* embodied in the Act. It therefore follows automatically that the profession must condemn the Act. Are we to be so misguided as to work an Act we have no choice but to condemn?

The position is simple. We know the Act is bad; we know we have the power to prevent it ever coming into force; and we know also we can compel an amended Act embodying our principles. Then let us do so without fear, since there are signs everywhere that the doctors are rallying and will stand fast. This letter is to appeal to any in doubt. There is nothing to fear except disunity. In unity our power is absolute and victory certain.—I am, etc.,

Tiverton, Devon.

R. E. J. PEMBREY.

For the Service

SIR.—In the spate of letters about the National Health Service many writers give their personal opinions as if they were the unanimous views of the profession. May I, therefore, for a start disclaim to be speaking for or expressing the views of anyone but myself. In the first place the overriding factor must be finance. I cannot afford, nor, I suspect, can more than a negligible percentage of my colleagues afford, to throw away my capital assets which have been acquired through many long and anxious years of toil. Yet this is precisely what I am invited to do by the Representative Meeting of the B.M.A. Unless I have misread the Act, those who decline to enter the Service on the appointed day forfeit all claim to compensation. Let us think earnestly upon this important point.

I understand that the B.M.A. has a fighting fund. How, may I ask, will that sum compensate all the G.P.s of Great Britain for throwing away their substance for the shadow of "freedom"? Do my colleagues really mean to tell me that they are prepared to make this colossal sacrifice? On the other hand, if we enter the Service we shall be in a much stronger position to argue. You cannot carry any weight in any institution of which you are not a member. If you wish to reform it you must first join and then use your *inside* influence for its reformation. I personally intend to do all in my power to make the new Service a success, not because I think it perfect, but because it is a beginning and can only be improved and amended by discovering its faults in the ordinary everyday exercise of our profession. Faults can only be pointed out when they have been shown by experience to exist, and they can then be rectified.

Personally, I feel with the other 52% who voted that way that the abolition of the buying and selling of practices is a good thing. Nor does the basic salary of £300 distress me. On the contrary, I am glad to think that my less fortunate brethren will be helped over the stile. The abolition of the basic salary would only swell the net profits of the big practices. *Per capita* the overhead expenses of a small practice are much higher than those of a big practice.

When two protagonists get up and go for one another I never believe that either is speaking the whole truth, nor does any thinking man. I do not share the gloomy prognostications of the B.M.A., nor do I swallow all of Mr. Bevan's rosy promises. At the meeting of the Metropolitan Counties Branch in B.M.A. House on Jan. 7, 1948, one man who sat next to me said to me: "Under this Act everyone will become a panel patient, and we know that panel patients are never as well treated as private patients." I was horrified. Anyone who takes such a drastic line to our great profession and plays right into the hands of our enemies. Personally, I think my panel patients are a far better deal as I don't have to worry about

To sum up: Let us all join the new Service and put our best into it and make it the finest medical service ever seen. The eyes of the world are upon us. Let us cease this unseemly wrangling and show ourselves men of public spirit with our patients' (as opposed to our own vested) interests at heart.—I am, etc.,

London, E.17.

ST. GEORGE B. DELISLE GRAY.

Resist Now

SIR.—If we are going to fight this megalomaniacal attempt to enslave the medical profession surely our past experience of dictators has taught us to fight with every means at our disposal, and to hit hard and often until victory is ours. To ensure a united front to the present Minister it is necessary for the B.M.A. to maintain the strong leadership which they have recently evinced, and by showing an understanding of the problems of all practitioners to bring over the waverers to our side.

Attack has always been the best mode of defence; therefore let the B.M.A. (1) insist that all medical members of executive councils, regional boards, etc., should resign *forthwith*, as suggested by Dr. Russell (Jan. 10, p. 72), and refuse to collaborate with the present Minister. (2) Counteract the Minister's inducement to the younger practitioner anxious to establish himself in practice but hindered by lack of capital, by immediately forming a fund from which money can be lent for the purpose of purchasing a practice or partnership—such money to be lent at purely nominal interest with easy method of repayment. Alternatively, establish a list of doctors who are prepared to accept payment out of income for a share in their practice. The younger man must be given his chance to vote on the Act without fear that a refusal means financial disaster to him. (3) Make it a definite part of our fight that the present Minister should be replaced by one who is more reasonable and whom the profession can trust.

It is ridiculous to ask us to fight when some of our professional brethren are already working on behalf of a scheme which we as a profession reject. Nor can one expect that the incentive of establishing a practice as held out by the Minister would fall on stony ground unless some equally attractive incentive is offered by those prepared to fight. Lip service alone is not sufficient.—I am, etc.,

Plymouth.

A. S. BRADLAW.

I.M.S. and N.H.S.

SIR.—It was a condition of the granting of compensation money for loss of career to officers of the I.M.S. that should they thereafter join "a permanent and pensionable Service under the Crown" the sum paid should be refunded to the Treasury except for a resettlement grant of £500. Since arriving in this country from India in early September last I have been endeavouring to find out from the powers that be in Whitehall whether the National Health Service will come under this definition. I first approached the Commonwealth Relations Office (old India Office), under whom I still technically serve, but after a month or so they disclaimed all interest in this matter and said it rested with the Ministry of Health and the Treasury. So the Ministry of Health has been requested to give a ruling, but, in spite of being pushed by the B.M.A., by my M.P., and by myself, can produce no better answer than that "the matter is receiving attention." To-day I have requested my M.P. to ask the question on the floor of the House at the earliest opportunity, as it seems time that the matter should be made public.

Now, my point in writing this letter is to warn all brother I.M.S. officers who are similarly placed to think carefully before committing themselves, and especially their capital, to any type of practice likely to be engulfed in the belly of the State. It seems to be causing a good deal of Ministerial head-scratching to decide the point raised, and personally I have no doubt that this should be read to imply that that head has in it a plan for an eventual fully salaried and pensionable State Service such as would come under the definition in question. Straws in the wind can give much information!—I am, etc.,

Leicester Forest East.

CHARLES F. GARFILL.

Years of Conscription

SIR,—“Conscripted, R.A.F.V.R.” (Jan. 10, p. 7), is in a similar position to myself. I was conscripted at the age of 23 and hope to goodness that I shall be out of the Army before I am 25. I was married at the age of 23 and shall therefore draw no more than half marriage allowance all the time I am in the Army. Further, my assistant M.O. and I spend the greater part of each day trying to think of a good sound way to shed our uniforms for ever, while doctors all around us are overburdened with work. Cannot something be done to get the young doctor out of the Services before it is too late and bone-idleness sets in for ever?

I have heard older doctors say that if a State service does come in it will be because the younger doctors vote for it. Not so, because the years of “conscription for no purpose” are the soundest pieces of propaganda against any form of controlled service where individual liberty is lost. As there is no appeal to the courts I would be glad if you would allow me to sign myself

CONSCRIPTED, R.A.M.C.

The E.M.S.

SIR,—In your leading article on “Consultants and the Act” (Jan. 3, p. 17), you quote Dr. Alan Wigfield:

“Whatever may be the case we must keep before us the possibility that sooner or later a political group for the time being in power may yet seek to introduce a State Medical Service,”

and you go on to say that “Dr. Wigfield has proved to be a safe prophet.” Dr. Wigfield’s letter was dated Dec. 23, 1939, and his protest was considerably weakened by the fact that he commended the E.M.S. proposals as a peacetime arrangement “which must commend itself to the majority of consultants.”

May I point out that Sir Ernest Graham-Little, in a letter published in *The Times* nearly three months previously—i.e., on Sept. 19, 1939—said:

“Supporters of the voluntary system—and they constitute the large majority of the medical profession—inevitably see in these arrangements (i.e., for the E.M.S.) the first step to a State Medical Service, which is one of the most conspicuous planks in the programme of a great political party. Surely the national emergency should not be used to cover an approach to so controversial a settlement as a State Medical Service?”

—I am, etc.,

Brookwood, Surrey.

H. M. STANLEY TURNER.

Medical Representatives in N.H.S.

SIR,—I think it essential that provision should be made for a proportion of the medical representatives on the various boards, committees, etc., to be elected by the profession in the various areas, etc., from the central board to local committees. Only in this way can we be certain that membership of these bodies is not a matter of political opinion. All boards, etc., should be entitled to elect their own chairmen.—I am, etc.,

Monmouth

P. G. HARVEY.

Municipal Doctors and the Plebiscite

SIR,—There is one point which, in my opinion, is fundamental, and which, if not given sufficient emphasis, may adversely affect the result of the plebiscite. It is this. The numerous practitioners at present in whole-time municipal appointments—either in hospital or local government service—should be assured not only of financial help but also of the Association’s active co-operation in preventing their posts being filled by other practitioners if, as a result of their undertaking not to enter the Service, they should on July 5 lose, however temporarily, their source of income.

Too often does one find practitioners holding such appointments who, although desirous of undertaking not to accept service under the Act as it now stands, are resigned to letting things go by the board—understandable, without the backing of the Association, in view of the necessity for bread-and-butter, but an attitude which could be just sufficient to destroy the unanimity of the profession’s determination not to accept service under the Act as it now stands or even to sway the vote in favour of the Minister’s scheme.

To ensure that such practitioners will, by their vote, agree not to implement the Act until amended the B.M.A. must stand behind them in the matters of security of tenure and of their financial commitments.—I am, etc.

London, E.11.

G. ELIZABETH KEITH.

A Binding Agreement

SIR,—I do not think that any of the fine words and rallying calls made in your correspondence columns upon the forthcoming issue facing the profession to be worth one whit unless we are prepared to back them up by a legal binding agreement signed individually by each one of us. Given a majority prepared to sign, we would then know where we stood in relation to one another. Even with a 100% plebiscite we would probably be jockeyed into another “1911.”—I am, etc.,

Shoburyness, Essex.

P. M. FEA.

A Party Political Issue

SIR,—As an individual with no very pronounced political leanings, and as one who could see more good than bad in the original Beveridge Scheme, I am grateful to Mr. Bevan for making it quite beyond doubt that I shall vote “No” in the forthcoming plebiscite, for two reasons.

First, he has made a party political issue of the whole scheme. His insistence that he must be the final arbiter without right of appeal, his insistence on part-payment by basic salary, the retention of his powers of indirect direction, and his stubborn adherence to the principle of expropriation of capital values of practices on his own terms cannot be regarded as anything but the arrogant declaration of political opinion. As an individualist, I have a personal antipathy to Socialist “collectivism.” I might, however, submit to its imposition with as good a grace as I could muster if I could see even one single instance of its success in the wider economic and social field of the country as a whole.

Secondly, the Minister has been—almost incredibly—careless enough to let fall the velvet glove at this stage in the matter of the right to practise midwifery. If this clause does not mean interference with the professional liberty of the doctor, what does? In this connexion I would express my unqualified agreement with Dr. D. C. Williams (Jan. 17, p. 121). I am one of the first to admit that the average newly qualified doctor is not a fully competent obstetrician, but unless he is also a fool he can always command more experienced professional advice in this country. The onus lies with the profession—with the examining bodies—for the necessary improvement in this respect, not with a politician.

May I also add my reinforcement to the views of Dr. H. J. Houghton (Jan. 17, p. 122)? If the present Government really wants to improve the amenities of the people, and particularly of those sections of the population whom it claims particularly to represent, it might well begin by assisting the profession to abolish the delays at present inseparable from hospital out-patient attendance, and the further delays, often of months, before in-patient treatment can be obtained by any but the most urgent cases. This will be problem enough in itself, but perhaps £66 million will go some way towards it.

In conclusion, may I repeat that I am not opposed to the introduction of a health service with 100% inclusion on a contributory basis. What I do oppose most strongly is such a scheme vitiated by unnecessary and vexatious political bias of no conceivable value to the persons whom the scheme purports to serve.—I am, etc.,

Chippenham, Wilts.

IAN MOORE.

Organization and Liberty

SIR,—The depressing tone of Dr. F. E. S. Hatfield’s letter (Jan. 17, p. 118) prompts me to make an urgent protest lest others should accept his axioms that “increasing organization can only take place at the expense of the individual’s right to do what he likes,” and that “the whole evolutionary process is in the direction of increasing organization.” The first phrase might have been more tersely expressed in five words: “Increasing organization spells individual frustration.” The second phrase would suggest that progress and “increasing organization” are synonymous terms. This pathetic fallacy

has surely been exposed by the downfall of Nazi Germany, the most highly organized State of the age, both socially and medically.

Let Dr. Hatfield, if he seeks a truly organized society, betake himself to the Prison Service and practise his medicine in an atmosphere where "increasing organization" has taken place at the expense of the individual to do what he likes; but let others of us, who value the freedom of the individual, continue to treat patients for the benefit of their health and not for the fulfilment of bureaucratic regulations. "Let us make an important contribution to this problem" by refusing to sacrifice our profession to the mercies of an ambitious doctrinaire Minister whose political theories breed the mentality that regards "rights" as personal benefits to be accepted without corresponding duties to society, and security as the height of ambition.—I am, etc.,

Weymouth.

D. J. ROSS STEEN.

The Word of the Minister

SIR,—Though many doctors may not be in disagreement with Mr. Bevan on the principles over which the Negotiating Committee are making a stand, yet the Committee is undoubtedly right in asking for a 100% "No" from each section of the profession to the working of a scheme many details of which seem to depend entirely on the word of the Minister only, and in which we have no appeal beyond Caesar to the civil courts.

One is given to understand that amount and method of remuneration and terms of service (whatever they may be) can be changed overnight merely by regulation and the Minister's signature. Therefore, until these details are cut-and-dried and in black and white by Act of Parliament, so that we know where we stand in the future, it would be professional and financial suicide to put our necks into a noose which can be tightened at the will or whim of the present or any future Minister. Also the public should be told at once clearly—so that there is no doubt in their minds—that we are not fighting against the inauguration of the kind of N.H.S. which we believe would be to their advantage, but simply against the dictatorship of a single man, or Party, on medical matters about which as technicians we have reason to believe that we know best. Let Mr. Bevan decide strategy by all means, but tactics must obviously remain in the profession's own hands.—I am, etc.,

Englefield Green, Surrey.

W. E. R. BRANCH.

Mr. Bevan's Attitude

SIR,—As reported in the *News Chronicle* of Jan. 14:

"Mr. F. Richards, chairman of the (Truro Council) Housing Committee, said it was a lack of courtesy on the part of the Minister (Mr. Bevan) that he should visit sites in the City without contacting his committee or housing officials. The first thing they knew about it was when they read of it in the Press. Afterwards alterations of houses were made without the Housing Committee being consulted."

Mr. Bevan's attitude to the Negotiating Committee was, I understand, in keeping with his behaviour reported above and clearly shows how he will deal with the medical profession when he has the power to do so—as he will have if we join under the conditions of the present Health Act, in which the Minister retains full power to elect chairmen of committees and ultimately to approve all members, lay and medical.

We must remember that there will be *no appeal* from any decision of the Minister or of a politically appointed tribunal of three persons consisting of a chairman (a barrister or solicitor) appointed by the Lord Chancellor, and two others appointed by Mr. Bevan himself. The only remedy is to vote "No" to service in the present Act and so defeat it, as Birmingham doctors did on Jan. 12 when their City Council proposed to extend municipal trading against the wishes of an overwhelming number of its retail traders.—I am, etc.,

Birmingham.

WM. WATSON NEWTON.

Alternative Proposals

It is stated that the present Act is rejected as completely unacceptable by a large majority and that general dissatisfaction with the ownership of their practices, are we to be asked to accept the Minister's alternative proposals? Any proposal that would be a threat to the whole community and

be such that all G.P.s would be willing to take part in it, whatever type of practice they now have. The essential feature of the scheme must therefore be to give all patients the time and attention now given to private patients, and to accept no lower standards. The overcrowded waiting-rooms and hurried, overworked doctor must be no more.

The number of public patients must be severely limited and the fees raised. I suggest a limit of 1,500 and a fee of 25s. for the first 1,000 and 20s. for the next 500. In addition, midwifery should be allowed, at a fixed fee per case. With the present number of general practitioners this scheme would not provide attention for the 45 millions at once, so I suggest that at first the service should apply only to persons of 18 years and over. Later the age could be reduced until the whole population is covered, but whatever happens the numbers for each doctor must not be increased.—I am, etc.,

London, W.8.

CHRISTOPHER L. CARTER.

The Public Interest

SIR,—Those who write and speak on the N.H.S. seem to have it well in the forefront of their minds that the public interest comes first; our own interests as a profession must then come second.

When a patient comes to us individually for advice we are bound first to tell him what we think best to be done; if he is unable or unwilling to follow our advice, we do not necessarily refuse to have anything more to do with him. It happens quite often in practice that satisfactory results follow the co-operation of patient and doctor in a line of treatment which may seem far from ideal to the latter. Might not a similar attitude of compromise prove helpful to both the public and the profession as a whole?

If the results of the proposed plebiscite are against us entering the National Health Service could we not take some such course as the following? We could explain our point of view to the public in the columns of the lay press and ask the public itself to signify if it would still desire us, in spite of our adverse vote, to co-operate with it in a scheme which we do not regard as being in its best interest. If the public does desire it, then we should naturally acquiesce. How far this suggestion is a practical one I do not know; but I do not think it is illogical.—I am, etc.,

Ditchling, Sussex.

F. WALLACE LINTON-BOGLE.

Hours of Work

SIR,—During all the correspondence about the doctors and the medical service I have not seen a single remark about the hours doctors will be required to work. Doctors are on duty or on call 24 hours a day; most of them work a good 10 hours a day and are often up several nights a week. Miners and railwaymen do a 44-hour week, as do most other workers irrespective of their profession or trade. I think it is near time the Negotiating Committee did something about this matter. I should appreciate the views of other medical practitioners.—I am, etc.,

Cambridge.

A. V. McMASTIFF.

Bad Law

SIR,—Another case of Satan rebuking sin—this time Mr. Aneurin Bevan warning the doctors against their judgment being "distorted by slogans." This comes ill from one who airily dismissed the reasoned misgivings of the Negotiating Committee with the slogan: "Hard cases make bad law." Actually, the elder statesmen of the profession have patiently contested the totalitarian intransigence of the Minister in order to convince him that, in this instance, the very reverse is the case—i.e., that a bad law makes hard cases!—I am, etc.,

Epsom.

A. H. GALLEY.

Money and Freedom

SIR,—Thank you for your leading article (Jan. 24, p. 153) entitled "Money and Freedom"—surely the most clear and true statement we have had. Close study will reveal, I think, that the very keystone of freedom is the retention of the goodwill of practice. Moreover, the freedom thus conferred will by no means be confined to the owners of goodwill but will be reflected throughout the profession. As a whole-time medical officer remarked to me the other day, "Your freedom is our

Ambulatory Treatment with
'AVLON'
brand

**PENICILLIN
OILY INJECTION**

The use of suspensions of penicillin in oil has proved to be a practical and effective means of delaying the absorption of penicillin after intramuscular or subcutaneous injection.

A single dose of Penicillin Oily Injection maintains bacteriostatic blood levels of penicillin for periods considerably longer than those which obtain when aqueous solutions are employed so that the necessity for injections to be given at frequent intervals is obviated.

The preparation thus presents a most convenient alternative to the multiple injection technique. The patient has the advantage of being on an ambulatory basis and of receiving only one or two injections per day.

'Avlon' brand Penicillin Oily Injection is issued as a homogeneous suspension in 10 c.c. vials, each c.c. containing 125,000 units of penicillin calcium salt.

**THE PRACTITIONER'S
CARD-INDEX GUIDE
TO TREATMENT**

Deliveries—
Early Feb.

Prepared and edited by medical specialists
experienced in medical publishing

This digest of treatment in the form of a card-index system is an original idea which is finding a ready welcome with the medical profession. A world survey of medical literature has been made and a digest, concise but sufficiently comprehensive to enable the reader to apply treatment, is supplied on cards filed in a special metal box. This is brought up to date every three months.

The complete Index consists of approximately 350 cards, including a list of pharmaceutical specialities with manufacturers' names and addresses and telephone numbers. The initial cost of £5 5s. includes four quarterly replacements of cards. Subsequently the cost of the replacement service is £2 2s. per annum.

As a reliable safeguard against infection, as a stimulus to appetite and as a nutrient tonic during all phases of rapid growth, Ostomalt is a most valuable aid. In addition to malt extract and concentrated orange juice, Ostomalt contains glycerophosphates and measured amounts of the therapeutically important vitamins A and D. There is no fishy oil in Ostomalt and no useless bulk; teaspoonful doses suffice. The 'completeness' of Ostomalt together with its pleasant orange flavour are decisive advantages when prescribing for children and convalescents. A regular daily dose is a material aid to the growth of healthy tissue and a firm defence against relapse.

freedom. The more free you are, the greater our negotiating power with our councils." It is not unlikely that Mr. Bevan's hidden appreciation of this truth accounts for his particular animus against the principle.—I am, etc.,

Wirksworth, Derby.

E. D. BROSTER.

Vacancies in N.H.S.

SIR,—According to Section 9 of the Negotiating Committee's memorandum (*Supplement*, Dec. 20, 1947, p. 142), it would appear that before a death vacancy can be filled the matter must be considered by (1) the Local Executive Council, (2) the Medical Practices Committee, (3) the Local Medical Committee, and that unsuccessful candidates may appeal to the Minister—as you say, a cumbersome and slow-moving business. I feel that it would be helpful to the younger members of the profession if you were to indicate the probable composition of his council and these committees.—I am, etc.,

Nettlebed, Oxon.

JOHN BRUNTON.

* The Local Executive Council consists of a chairman appointed by the Minister and 24 other members, of whom 4 are appointed by the Minister, 8 by the local health authority, 7 by the Local Medical Committee, 3 by the Local Dental Committee, and 2 by the Local Pharmaceutical Committee. The Medical Practices Committee consists of a chairman, who must be a medical practitioner, and 8 other members of whom 6 must be medical practitioners, and at least 5 of these 6 must be actively engaged in medical practice. All are appointed by the Minister. The Local Medical Committee is a committee formed in the area of an Executive Council to represent medical practitioners of that area and accepted by the Minister as representing them.—Ed., *B.M.J.*

Financial Struggle

SIR,—After the recent glut of letters I do not want to add to your troubles, but I should like to stress one further very important point. What is going to be done for those medical men who, as the result of the war, are financially unable to join us in opposing this State monopoly in medicine?

I do not refer to those eligible youngish men who went for a few months at the end of the war, forced into it against their will, having sheltered themselves so far in some "indispensable" post. They lost nothing tangible, for they were not away long enough to matter. Being very careful men, they saw to it that their colleagues at home did not spare themselves on their behalf. No, I mean the real men, the faithful men—the men who gave up practices, wives, and families, etc., simply because they thought it was their duty.

Some of the elderly came back to find their practices almost disappeared. Others have recently bought practices and are just beginning to emerge from financial difficulties to be faced with the present crisis. Others, younger, are just biding their time, but cannot wait much longer on account of a wife and young family. Most of them loathe the thought of a salaried State medical service, but what is going to happen to them?

I have read the leading article entitled "Why Be Fearful?" (*Jan. 17*, p. 104) and seen other vague references to temporary help for them. They want to know something definite and to be relieved of their anxieties. Could the B.M.A. come forward with a real scheme of concrete proposals, and let these men sleep easily at night? It will have to be done tactfully, for these men are proud men, or we should have heard much more about them.

It is due to them if we expect them to wait and come in with the rest of us. Otherwise they are going to be forced by circumstances, and against their own wills, to form one thin wedge for our dictator's purpose. That title is not bred of my emotion. It is only too true, and fits the man and his doctrines. We cannot afford to give him many wedges, and that is why I am so anxious to see some definite policy emerge now. It will be too late after the plebiscite.—I am, etc.,

Hampstead.

H. V. DEAKIN.

Doctors' Lists in N.H.S.

SIR,—I should like to draw your attention to what seems to me to be an incomprehensible anomaly contained in the Negotiating Committee's statement to the Minister, recently circulated

to all doctors. This particular point has not, so far as I know, been brought up in the correspondence in the *Journal*.

In para. 41 of its report the Negotiating Committee states: "On and after the appointed day a proportion of the population will sign on doctors' lists. Of the remainder, a proportion, varying in different areas, will sign on doctors' lists when the need arises to consult a doctor." Now it appears to me that if the last sentence he correct there will be no obligation on patients to sign on with a doctor until their first illness after the appointed day, when they will be immediately entitled to free treatment. Naturally then, knowing this, no patient will trouble to select a doctor until the first time that he needs one, for he can at any time present his card and get free treatment, without the bother of a preliminary visit merely for the purpose of registration. In other words, the doctor's list will be only gradually compiled, being made up of such persons in his district who have fallen sick and consulted him, as and when they do so.

At this rate it will take years to build up a sizable practice. The whole basis of payment by capitation is surely the fact that a large proportion of the patients insured are never ill at all for long periods. Those seeking advice soon use up more than their capitation fee's worth of the doctor's time, and one's income depends, in effect, on one's well patients.

Surely, Sir, it should be a simple administrative procedure to ensure that every member of the population selects a doctor by a given date, before the appointed day. They have to select a butcher and a grocer, so why not a doctor? Then, on the appointed day we shall know exactly where we stand and how much our first quarterly cheque is likely to be. Under the Negotiating Committee's arrangement it will be small or non-existent. A simple measure to ensure that patients do, in fact, get on a doctor's list would be a provision that everyone who fails to do so by the date given will not be entitled to free medical treatment for three months after he first registers with a doctor. Similarly, persons moving to a new area, or babies born, should be given a reasonable time, say one month, in which to register on a doctor's list, failing which they also may be charged fees for the first three months.

At the present time this iniquity still exists in the N.H.I. scheme. Here is a unique opportunity to end it once and for all.—I am, etc.,

Morden, Surrey.

ARVID SAUDEK.

National Health Service

SIR,—At this eleventh hour, when all that our profession stands for is at stake, a brief recapitulation of events may not come amiss. The National Health Act was placed on the Statute Book by a Minister who had not the courtesy to consult those who would be primarily responsible for working it. At the ensuing plebiscite the profession showed very clearly that it disapproved most strongly of this legislation as it stands and refused to negotiate. Then, by whose mandate it is not clear, the heads of the Colleges advocated negotiations with the Minister. The profession, having already expressed its opinions in no uncertain way, made a complete and pusillanimous *volte face*, and the sorry spectacle was seen of our representatives going almost cap in hand to negotiate with a man who never had the slightest intention of conceding anything and who is relying upon his hoped-for success in regimenting the doctors to offset the dismal failure of his housing programme and preserve his political "face" at all costs.

Let us be quite clear what it is that this Mr. Bevan hopes to do. He will compel the sale to him, at a price as yet unspecified, of the goodwill of our practices, so that to sell to anyone else what we have built up by our own hard work will become a crime. His talk of "buying and selling patients" is, as he well knows, arrant nonsense, for anyone who has ever bought a practice knows very well that the patients he has "bought," both private and panel, have complete freedom to go elsewhere if they so desire.

He will tell the doctor where he may or may not set up in practice, and, what is far worse, he will decide whether a doctor shall or shall not be retained in the Service. From this decision we are told that there will be no appeal. He will attempt to make our allegiance primarily to the State and not to our patients.

Let us in heaven's name unite as never before and refuse to be cozened out of all we hold dear by specious arguments based on nothing but political expediency. Nothing less than our freedom and the freedom of those who come after us is at stake. Let us show this man, who would be our master but who is in reality our servant, that, though likened by him to fruit, we will refuse to be plucked, whether ripe or green. Let the faint hearts who fear that they will suffer financial loss if they do not answer "Yes" take courage. We hold the cards, and if we play them the Act cannot be worked and the financial loss will not arise. Let us therefore answer the plebiscite with yet another resounding "No," for only by so doing can we continue to preserve our self-respect and the traditions of a great calling in refusing to become the salaried lackeys of a demagogue.—1 am, etc.,

Andover, Hants.

J. LEIGH COX.

SIR,—The medical profession as a whole is far from unsympathetic towards the establishment of a national medical service, but they are (and I hope will continue to be) very much opposed to virtual dictatorship from the present or any future Minister of Health. I am one of very many medical men who willingly, and at personal loss, served their country during the war years, putting the interests of the country before those of the individual. Can Mr. Bevan not now learn to subjugate his own personal views and interests to those of his country? The medical profession have always been most unselfish in their devotion to duty and the care of the general public. Surely this generous public-spiritedness should be fostered and not smothered.

Not even a criminal is denied the right of appeal against any conviction. Is it then not an insult to the intelligence of the members of the profession that they should be expected to support a service from which the Minister of Health may dismiss them with no such right of appeal? This is surely too unreasonable for any sane person to suppose, yet Mr. Bevan seemingly thinks it possible. If Mr. Bevan can't co-operate with the profession to get the best possible service for the country, then I suggest that the present Government appoint another Minister in his place. The scheme is of too great value to the country as a whole to have it wrecked in its inception by any individual so dictatorial as the present Minister—himself proving the greatest stumbling-block in the way of a service which the profession would welcome if properly conceived.—I am, etc.,

Keith, Banffshire

J. LENNEL TAYLOR.

SIR,—I notice the letter (Jan. 17, p. 120) signed by eight doctors present at a meeting of doctors practising in "Fleet and the surrounding district." Two practise in Basingstoke. The *Medical Directory* for 1944 gives the number of doctors in Fleet, Basingstoke, Farnham, Farnborough, Camberley, and Aldershot as 135, so that we can scarcely assume that the eight are representative of the district. The same applies to most of our local meetings, where the militant opponents of the Act attend most regularly, and they in turn elect our representatives. This was demonstrated by the former plebiscite, which showed that the majority of the doctors refuse to be controlled by the militant minority.

The Act is to come into force on July 5, and plans are being carried out rapidly so that the switch-over can be done efficiently. The medical representatives have been elected upon the executive councils, and are bound in honour to work upon the councils to make the Act successful, and for that reason they should encourage their colleagues to accept service.

I have been in practice since 1904, and have welcomed the great improvements in preventive medicine. Since 1904 we have established school clinics, infant-welfare centres, ante-natal and post-natal clinics, and a tuberculosis dispensary. The old poor law has passed, and the workhouse has changed into the general hospital. In the counties we have seen the building of better and efficient hospitals under the council.

When the National Health Insurance Act came into force in 1912, I remember the Area Committee before the Act was passed. I was a member of the B.M.A. Committee, how we

the debacle in the last days of December, 1911. Those anxious days in the beginning of January until we were released from our pledge by the B.M.A. and signed on are still vivid in my memory. I have been a member of the Panel Committee since the beginning, and their representative on the Insurance Committee since 1931, and am now vice-chairman of the Finance and General Purposes Committee, and can vouch for the cordial relations between the Insurance Committee and the medical profession.

I have been a member of the committee of the Borough of Reading Medical Society since we established it in 1911 in order to attend to the dependants of insured persons and others. In 1939 we bought a building in the centre of the town, partly rebuilt it, and have as our tenants the Reading Insurance Committee, the Berkshire Medical Society, the Reading and District Dental Service, and other bodies, in anticipation of the extension of the National Health Insurance Act.

I am convinced that this National Health Service Act will prove of great benefit to doctors and patients alike and to the country as a whole. There are certain defects over-emphasized by the opponents of the Act which can be remedied after a fair trial, when the atmosphere is more peaceful. In the meantime I shall uphold my freedom to join in July, whatever the decision of the B.M.A. may be.—I am, etc.,

Reading.

S. GILFORD.

Natural Position for Childbirth

SIR,—An Englishwoman born in Hammersmith went out to Australia. She there met a Pathan from Afghanistan, a horse-dealer and camel-driver. She married him and went home with him to a place in Afghanistan just beyond Ghazni. She was his only wife, and contrary to Eastern custom she always ate with the men. Women in the East usually prepare the food and eat after the men have finished. When travelling they were in tents, but at home in a village they lived in a one-story house made of adobe (mud and straw) with a flat roof. Two rooms below and the floors were of beaten earth, the roof was flat. One room, the inner one, was the man's room; the other was for the family.

This woman was 29 when her first child was born and she had seven children. She was delivered in the native way. (She is now a fully trained midwife.) Plenty of hot water was available both day and night and was kept in tall copper jugs with spouts but no handle.

The women are very clean. They are Mohamiedans and wash five times a day before prayers. They also wash even after passing urine and keep their hands very clean to knead bread, prepare meal, etc. They walk about as usual until labour pains prevent them; then a ring of twisted cloth is made for them to sit on like the roll they make to carry a basket or water pot on the head.

Three women were present with hands well washed. The expectant mother squatted on the ring of cloth supported by a woman at the back and one on either side. The one behind sat with knees apart and held the knees of the parturient woman. Women at either side held knees or arms or hands of the patient as needed. Another woman waited in front to take the baby as it emerged. There was no touching, interference, or examination of any kind before, during or after the birth. The women just waited until the child was born. She says she saw hundreds of cases and the perineum was never torn, but she complains that the pain was like "the pains of hell which encompassed me." She remained in the same squatting position, while the woman in front, who had taken the baby as it emerged, waited until pulsation in the cord had ceased, then cut it. She left the maternal end to bleed but tied the foetal end with a bit of rag. There was no massage of the abdomen. They waited, and after two or three minutes the patient coughed and the placenta came away.

She had seven children, and with the last—a fine boy—she was quite alone, and so squatted on the ring of cloth and placed her back against a wooden support holding up the roof, and as the head emerged she "slithered off the cloth ring" on which she was squatting on to her back on the ground so as not to hurt the child. She then sat up, cut the cord herself, and the placenta came away with no trouble. She washed the baby with muslin she had boiled. Three hours later her husband brought water and soap for washing.

The Afghan women were all confined in this way, squatting on the floor. In twelve years she only saw one case of puerperal fever—a rich girl, daughter of the Governor of Ghazni. No doctor or midwife to be had—and one case of death due to locked twins, she thinks. Our informant never saw any trouble in childbirth among the Afghan or Powindah people.

no displacements of uterus, no breast abscesses, no perineal tears. These people are the ones who travel into India with horses to sell. The women ride astride, gallop about, and show off the horses' paces. I have taken snapshots of these girls in India on their horses.

The girls have their periods at 12, 13, or 14. Then they cover their faces and are considered unclean. But they are quite free

FIG. 1

FIG. 2

to go about and are never assaulted by men, because the father would kill him at once. Result—no illegitimate births, no courtship, no walking out. The father finds the husband for them. There is no adultery. Dancing takes place at the birth of a son (silence is considered befitting the birth of a daughter as in India). Everyone dances, the men by themselves in the street, the women by themselves in the house. These dancers are of another tribe and have a morality of their own. No man would be allowed to see a confinement. This would be considered most indecent, for "this is women's work and must be kept for them only."

I enclose photograph (Fig. 1) of a girl in the confinement position sent by Dr. Stephens, of Ilorin, Nigeria. It will be seen it is precisely the same as that depicted on an ancient Peruvian piece of pottery (Fig. 2) and the same as illustrated Plate XI in my book, *Safe Childbirth*—in fact the natural posture for childbirth as practised from prehistoric times.—I am, etc.,

London, N.W.11,

KATHLEEN VAUGHAN.

Chronic Ulceration after Irradiation of Wart

SIR.—Mr. Mortimer H. Shaw's article on chronic ulceration after irradiation of plantar wart (Jan. 3, p. 11) has reminded me again to my continual surprise that patients are submitted to numerous treatments by irradiation for plantar warts. In my experience the treatment of this condition by CO₂ snow is so simple, safe, and efficient that it can be undertaken in the out-patient department or consulting-room with the greatest of ease by use of an ordinary CO₂ outfit.

The essential part of the treatment is to raise a blister between the epidermis and the true skin so that the wart is lifted up with the epidermis. At the end of a week the blister is cut away with the wart in the centre of it (with the usual aseptic precautions), and the depth of the dimple which the wart leaves in the floor of the wound gives some indication of the degree of pain it must have caused.

The snow pencil should be firmly applied over the wart for from five to seven minutes (exceptionally 10 minutes), but even in children the skin of the sole is so thick that the necessary blister will not form unless the wart and the surrounding thickened skin have been pared with a razor or sharp scalpel to a depth where the individual fronds of the wart are seen in cross-section, and on occasions even a small capillary opened in the wart. This is quite painless and requires no anaesthetic. The application of the snow varies in the amount of discomfort it causes, but even in children the treatment can be carried out without causing excessive discomfort.

A small protective dry dressing is applied with strapping, and if an adequate blister has not formed after a week the skin

should be further pared down and a second application of snow made for the same period. A dry dressing is applied after cutting away the wart and blister and can be removed after a further week, when healing should be complete. The patient is fully ambulatory throughout.

As I have never known it to fail the only reason that I can think of for this simple treatment not being more generally adopted is that insufficient paring of the skin has prevented adequate blister formation, and the method and not the technique has been blamed.—I am, etc.,

Rochdale.

A. M. McMASTER.

Convulsive Properties of Thiopentone

SIR.—I feel sure many of us are grateful to Dr. R. L. Wynne (Jan. 10, p. 48) for putting forward a theory of causation of the convulsive movements and tremors that not infrequently accompany induction of anaesthesia with a barbiturate by the intravenous route. The phenomenon is also seen when hexobarbitone is used, although this drug, so far as its side-chain structure is concerned, does not so closely resemble the convulsant barbiturates cited as does thiopentone.

One feels, however, that it is not necessary to postulate a convulsant action—i.e., a stimulant effect on motor nerve cells—on the part of thiopentone to explain these manifestations. The pronator activity is especially marked in, and often confined to, the arm in which the injection is made: it seems almost a purposive effort to get the needle out of the vein, suggesting that it is a withdrawal reflex which becomes manifest when consciousness is lost. During the conscious phase the movement is suppressed either totally or almost completely.

It seems reasonable to suggest that these movements represent the second stage of anaesthesia, when the activity of lower motor centres becomes evident as a result of their release from cortical control; when these lower centres are depressed by deepening anaesthesia to stage 3 the movements cease. It is to be expected, therefore, that this phenomenon will be more commonly seen when premedication has been inadequate or ineffective and the lower motor centres are accordingly more active than in a well-sedated case. Muscular, highly trained males leading an open-air life are especially liable to fall into this group. It is not to be anticipated in such cases that a barbiturate alone will provide good relaxation at a level of anaesthesia short of severe respiratory depression. If the tremors were due to a convulsant property of thiopentone it would be expected that increasing the dose would lead to enhanced severity of the movements, but this is not the case.

A close parallel to this action of intravenous barbiturates is the so-called "stimulant" action of alcohol, where the differential depression of the highest centres leads to a phase of enhanced activity on the part of lower centres.—I am, etc.,

Barnet, Herts.

C. F. SCURR.

SIR.—Those of us who make frequent use of the intravenous barbiturates must have welcomed Dr. R. L. Wynne's paper on the convulsive properties of thiopentone (Jan. 10, p. 48). The following observations may also be of interest. When dealing with Army patients I acquired the habit of giving thiopentone rapidly (0.5 g. in less than a minute and maintenance doses at a similar rate). Many of these patients showed pronation of the forearm as described by Dr. Wynne; these and other limb movements often appeared to be a response to surgical stimuli and were attributed to light narcosis. Later a sample of hexobarbitone ("evipan") was found in some German equipment, and this was used in similar dosage and rate. The results in three fit soldiers were surprising, and fully comparable to those described by Dr. Wynne as the "shudder reflex." Further injection of comparatively large doses of hexobarbitone had no effect on these movements, but the inhalation of ether vapour soon stopped them, and the operation could be started. The movements seemed to occur as a response to a surgical stimulus.

In a few similar cases hexobarbitone was given at the rate of one minute to each ml. and no "convulsions" were seen. It was then decided to try thiopentone at the rate of 20 to 30 seconds to each ml. of 5% solution, with the result that muscular contractions were no longer observed. Incidentally much less thiopentone was required for each case.

More recently, when dealing with lists containing several minor cases, an attempt was made to save time by giving an

estimated dose rapidly and continuing with nitrous oxide and oxygen, if necessary by passive ventilation. On several occasions this technique caused hiccup, which could only be stopped by adding ether. A return was made to a slower rate of injection (2.5 to 3 minutes for 0.5 to 0.7 ml. of thiopentone), and diaphragmatic spasm was no longer seen.

Statistical evidence is unfortunately lacking, but a strong clinical impression was formed that the "convulsive" effect of thiopentone is closely related to the rate of administration. It would be interesting to know at what rate Dr. Wynne gave his thiopentone, and whether in the case that he reports it was given at the same speed on each occasion.—I am, etc.,

Barkeley, Cheshire

C. T. BARRY.

Orchitis of Mumps

SIR.—In the article by Dr. Desmond Laurence and Mr. Donald McGavin on the complications of mumps (Jan. 17, p. 94) decompression of the testis is, I think, too lightly dismissed. It is disappointing to see the damage done to the testes by the orchitis of mumps assessed by the degree of atrophy and sexual vigour and not on semen analysis, which would have revealed grave impairment in many of these cases. Biopsy frequently shows extensive or complete spermatogenic atrophy with no lessening of virility.—I am, etc.,

London W.C.1

REYNOLD BOYD.

Fatal Air Embolism

SIR.—I would like to add the following case of fatal air embolism to the literature, following the case reported by Hewer and Coombs (Jan. 17, p. 97).

In October, 1946, a man fell off his bicycle in Camberwell and was admitted to hospital, where he was found to be suffering from a fracture of the right acetabulum. He was transferred to a sector hospital, where traction was applied to the femur. He was in very great pain, and further x-ray examination showed that a sharp piece of the acetabulum was adjacent to the bladder. It was decided to replace the fragments of the acetabulum digitally through an abdominal incision.

The man was in agony, and he was brought to the theatre in his bed on wheels under the influence of morphine gr. 1/6 (11 mg.) and atropine gr. 1/100 (0.65 mg.). Gas and oxygen were administered on the bed, and subsequently with the aid of ether and carbon dioxide blind intubation was performed. The patient was then transferred to the table and the operation commenced with the patient in Trendelenburg position. The fragments were replaced satisfactorily and the operation was uneventful until, as the peritoneum was being sutured an hour and a quarter later, the respirations ceased and the temporal pulse was no longer palpable. The face immediately became greyish-blue in colour. The table was brought to the horizontal and artificial respiration commenced in association with forced respirations through the anaesthetic bag. Adrenaline was injected intracardially without response.

Post-mortem examination revealed that the right side of the heart was bulging, and when the right auricle was incised air escaped. There was a very small quantity of pink blood in the auricle. The thoracic line was found to be fractured and a sharp fragment was lying under the femoral vein. This could well have been the site of the air entry when the peritoneum was pulled upon.

—I am, etc.,

Uxbridge, Middlesex

T. DAVID LAMBERT.

Digitalis in Chronic Heart Disease

SIR. It is usual to find in acute wards digitalis applied in cases of auricular fibrillation. There it is usually given in large doses until effective blockage is achieved. In other cases of heart disease digitalis is usually omitted. This way of applying digitalis is not satisfactory in old age. The old muscle being either atrophic and brown or flabby and fibrous could never tolerate a treatment with doses used in middle age.

Cardiac failure in old age is of more complex nature. The condition old people suffer from, frequently termed senile cardiac failure, is not due only to infective organisms. In the presence of heart failure congestive bronchitis and congestive pneumonia are prevalent. In addition long-sustained recumbency causes fracture of neck of femur or senile hemiparesis and pneumonia. The old person suffers from hypostasis and hypostatic pneumonia. The failure of the heart is caused not only by cardiac weakness but also by venous congestion but also by senile paralysis of the heart and a reduction in the output of urine and promotes

accumulations not only of sulphonamides but of other drugs as well, and makes it necessary for us to apply what I can only call infant-doses in many cases. That is why small doses of digitalis appear to be effective in senile cardiac failure.

In cases where normally high blood pressure of old age is going down to the norm of middle age and other signs of cardiac failure supervene a very small dose of digitalis will be sufficient to correct decompensation—for instance, digitalis 1/2 gr. (32 mg.) b.d. or even a smaller dose. In cases where the systolic B.P. approaches the diastolic pressure or the diastolic pressure sinks down to 70 somewhat larger doses used will prove very effective. Only cases of infarction may be excluded there. In these cases we do not use the blocking power of digitalis—blocking the senile heart which is already in a state of disposition to blockage naturally being dangerous although it seems to me that less danger comes from a blocked heart than from medical narcosis. With regard to life expectancy, we are trying to use the inotropic action of digitalis on the heart, its direct action on the heart muscle or what is left of the muscle (a part of it substituted by fibrous tissue). The force to be applied to bring the old motor forward, without causing it to crumble down, depends entirely on the judgment of the treating physician—or otherwise, plainly spoken, the way that art is used.

There is no doubt that treating old patients involves a certain amount of chance being taken. If one loses the patient or may fear for reputation, or wastage of drugs, but one will find consolation in those many one will be able to help and some times to bring on their feet again—at least to overcome the crisis. One will be astounded how quick the response of an organism occurs in many instances.

We mentioned above that senile pneumonia is a term comprising conditions of a very complex nature. It is important to know that the temperaure does not give us any clue in supporting our diagnosis in old age. Old people have usually subnormal temperatures under normal conditions. A temperature of 98.4° F. (36.9° C.), which is considered to be still normal in middle-age, already indicates a rise, and the temperature of 100° F. (37.8° C.) therefore will be considered as being relatively high in senescence.

In view of this fact bacteriological examination of sputum germs, especially with regard to sensitiveness to penicillin, will be an important measure to determine severity of accompanying infection.—I am, etc.,

Carlisle.

W. WEISS.

Penicillin and Blood Coagulation

SIR.—The investigations carried out by Sir Alexander Fleming and Dr. E. W. Fish (Aug. 16, 1947, p. 242) go to show that the effect of penicillin on blood is to retard coagulation. I cite the following case to request an explanation.

A boy aged 11 was brought to me on Jan. 10, 1946, for bleeding from nose and mouth. The trouble had started eight hours previously. He had been operated on elsewhere for enlarged tonsils and adenoids a week before, and at that time bleeding had ceased within a few hours. He had already received injections of calcium gluconate and "coagulen-Ciba," but with only little and temporary effect.

On examination the tonsillar bed was found to be clear, so blood was evidently coming from the adenoid area, and one could see blood oozing out from behind the soft palate. The nose was not at fault. Injections of calcium gluconate, coagulen-Ciba, and ascorbic acid were given at 10-minute intervals, with only temporary effect.

As these late bleedings are often due to secondary infections the patient was given 20,000 units of penicillin intramuscularly. Bleeding stopped within five minutes. The same dose of penicillin was repeated three-hourly until a total of 100,000 units was given. Next day, 26 hours after the first injection of penicillin, bleeding started again. As the patient had already received 100,000 units of penicillin, he was given injections of coagulen-Ciba, ascorbic acid, and vitamin K, without any effect. Bleeding gradually became profuse and alarming. Intramuscular injection of penicillin, 30,000 units, was given. It acted like magic. Gradually the bleeding became less severe and stopped entirely within 10 minutes. Injections of 20,000 units of penicillin were repeated at three-hourly intervals until a total of 400,000 units was given. There has been no recurrence of the complaint.

Now, one would like to have information on the following points: (1) Did penicillin have any direct effect on the

coagulation time of blood? (2) Or, Did it help the coagulant drugs by combating sepsis? (3) And, if so, could the effect be so rapid?—I am, etc.,

Ahmedabad (Bombay Province), Indian Union.

H. M. DESAI.

Renal Function in Disease

SIR,—The *Journal* of Jan. 3 (p. 22) contains extracts from an address given by Prof. Robert Platt before a meeting of the Manchester Medical Society on Dec. 3, 1947. These extracts raise problems of considerable interest, especially to those concerned with the clinical application of fact and theory. With your permission I would put forward the following points which arise out of the published context.

1. Rose Bradford has shown that surgical removal of most of the kidney caused the remainder to secrete copious, dilute urine of low specific gravity. Prof. Platt expresses the opinion that it was inconceivable that in the circumstances the remaining nephrons should suddenly have developed tubular failure. Might it not be suggested that it was even more inconceivable that such a delicate and highly specialized system as is the nephronic system could fail to be disorganized if the whole were mutilated by the extirpation of a major part? The kidney is a vital organ, and is fashioned by Nature to act physiologically as a separate and distinct unit. The traumatic effect of such vivisection must be taken into consideration when assessing the function of the portion of kidney left *in situ*. Further, is it known for how long the surviving section of the kidney showed the defect in function? Was there any attempt at recovery with improved function? Or did the death of the remnant and/or the subject supervene too soon?

2. More recent investigations have shown that the filtration fraction in chronic renal disease was high, which suggested that there was in fact a high glomerular pressure. But assuming that the glomeruli are themselves involved in renal disease, one must infer that Bowman's capsules must also be involved with a corresponding disturbance of their contribution to the filtration fraction. Is it not possible that in the pathological process filtration becomes leakage, independently of pressure in the glomeruli? If the synovial membrane of a joint becomes damaged or diseased an increased amount of fluid appears in the joint cavity. Does not this suggest a raising of the filtration fraction of the synovial membrane?

3. Prof. Platt states that glycosuria was never present in chronic renal disease. Would this still be true if a patient with chronic nephritis suddenly developed diabetes? It is difficult to see why the blood should wish to give up its normal natural sugar content just because the kidneys were diseased. Are the kidneys controllers of the sugar content of the blood in health? In diabetes they do try to get rid of the excess of sugar which they regard as a waste product, and which as such it is their function to excrete.

4. Prof. Platt states that the histology of chronic nephritis showed in general that in those areas where there was tubular atrophy the glomeruli were non-functioning. Does this mean that the glomerular capillaries were occluded, and that no blood was passing through? If so, at what stage of tubular atrophy did the glomeruli cease to function, whether as filter or leak?

5. Finally as to the question of oedema in acute nephritis. Could not this be approached from the angle of obstruction to the return flow of body fluid from the tissues back into the general circulation? The vascular system is fixed in capacity; the body fluid is not only in constant circulation, but requires constant replacement from without. Hence the necessity of a free and constant overflow from the vascular system. The main overflow is situated at the kidneys. If this is obstructed, as in acute nephritis, then the return flow of fluid waste from the tissues back to the circulating system must also be obstructed, with the result that it becomes dammed up in the tissues—hence oedema—or is this altogether too simple?

R. G. BLAIR.

Varicocele of Canal of Nuck in Pregnancy

SIR,—As I can find no mention of this condition in any of my textbooks, it seems to me that this case may be of interest.

In September last I saw an expectant mother, 2 para, aged 34, then 5 months pregnant, with a left inguinal hernia, soft and easily reducible, about as large as a pigeon's egg. There were three possible times to deal with this—at once, post partum, or when the child was viable. I discarded the first for fear of miscarriage, and the second because of the necessary interruption of the child's upbringing, and decided to operate at the 36th week.

On Dec. 30 I operated and found that the hernia was a large varicocele intimately surrounding the round ligament in the canal of Nuck. I ligated both ends and removed the mass, closing

the inguinal ring in the usual way. Within 12 hours the patient was in labour, and she delivered herself of a 7½ lb. (3.5 kg.) baby quite normally.

To my great surprise, she was quite unconscious of any discomfort in the operation wound throughout labour, except when I grasped the fundus uteri during the third stage. Puerperium was quite uneventful. I was very much struck by the complete absence of any discomfort at the inguinal ring during the violent expulsive efforts of labour, and also by the prompt oxytocic effect, presumably of interfering with the round ligament.

I am now speculating whether the varicocele was a temporary result of pregnancy which would have spontaneously cured itself after delivery, or if I did in fact do the correct thing.—I am, etc.,

Sheborne, Dorset.

RICHMOND MCINTOSH.

Intravenous Alimentation

SIR,—Dr. H. E. Magee is to be congratulated on his very lucid article (Jan. 3, p. 4) on this very important subject. In my own work on this subject (*Med. Pr.*, 1947, 217, 497) I have confirmed most of the points made by Dr. Magee. I have had considerable clinical experience in the use of intravenous amino-acid mixtures—all made in America—and I can confirm that nitrogen balance can be restored readily in conditions where nitrogen loss is considerable—e.g., in trauma, after operations, and in infections.

Reactions in my series do not appear to occur in more than 1% of cases treated, a figure which compares favourably with transfusions of whole blood or plasma.

Thrombosis has occurred where more than 1 litre has been given into one vein only, but I have had no trouble where I adopted the American technique of giving large amounts in divided doses into several veins—not more than 300–500 ml. being given into any one vein. It must not be forgotten however, that amino-acid mixtures are by their very nature excellent culture media, and particular care must be taken to avoid contamination, and the intravenous technique must be as aseptic as possible.

Most commercial preparations contain pyrogens, and it is advisable to have batches of the solution tested for these before use. There can be no doubt that an appreciation that ten of the amino-acids are essential—that is, not replaceable by any of the other amino-acids—is fundamental in this form of therapeutics.

I would therefore suggest that we abandon the present method of saying that so many grammes of protein are required by a patient in any given condition. After all, many proteins do not contain all the essential amino-acids, or the amounts contained are so small as to be of no value. Finally, it would seem that certain specific conditions—e.g., hepatic failure—require larger quantities of amino-acids, such as methionine, than do normal healthy individuals.

What is required, in my view, is an authoritative statement on the total amino-acid requirements of any given patient rather than the total protein. Perhaps it may be possible in the near future to supplement this information with a table giving the total daily requirements of each essential amino-acid in health and disease. With this information in our hands we have available one of the most important therapeutic advances made in recent years.—I am, etc.,

Southport.

JOHN H. HANNAN.

A Sign of Carcinoma

SIR,—The very useful manoeuvre which Mr. A. Dickson Wright describes (Jan. 3, p. 27) has been in use for some time. It is described by Auchincloss in Nelson's *Surgery*. In the same place is described another method of accentuating some of the physical signs in the breast. The patient is made to kneel with the arms forward on a support. The breasts then fall into a pendulous position, so that the relations between the tumour and the chest wall are clearly demonstrable. Some breasts may be transilluminated with advantage in this position. I have found both the manoeuvres most informative and have often regretted that they were not taught to me when a student.—I am, etc.,

Hull.

J. CLAPHAM COATES.

Leprosy and its Problems

SIR.—Dr. Niels Dungal's letter (Oct. 18, 1947, p. 631) raises the question as to whether other insects besides cockroaches may transmit the disease and suggests that lice and fleas are more likely to be the instruments of transmission than any other. It is quite possible that different insects may be the vectors in different parts of the world—i.e., acting as true intermediate hosts, in which a stage of development takes place rendering the bacilli infective to man.

Ehlers, Bourret, and Wirth investigated lice and fleas in 1911 without coming to any definite conclusion. Flies, ticks, bugs, mosquitoes, scabies (acari) have all been examined as possible direct carriers of infection, but I do not think that any attention was paid to the possibility of any of the insects acting as true intermediate hosts, and certainly no inoculation experiments of infected faeces of insects into man were carried out. I am of opinion that such experiments are the only means by which the mystery of transmission will be solved.

Cockroaches date from carboniferous times and existed all over the world, the climate being hot and moist. The species *lapponica* was the most common variety in Europe in the sixteenth century and dwelt in woods and thickets, and is still found in the mountains of Norway and Switzerland as high as shrubs extend, and when sheltered by human dwellings can endure the extreme cold of the most northern parts of Europe (Miall and Denny). Is it not possible that cockroaches have existed all along in Iceland?—I am, etc.,

Nairobi, Kenya.

BERNARD MOISER.

A Suggested Hospital Unit

SIR.—Having read with interest the correspondence concerning the plans suggested by Mr. H. J. McCurrieh (Nov. 22, 1947, p. 832), and in particular his letter in the *Journal* of Jan. 10 (p. 77) in which he mentions the contradictory advice which he has received "from persons of no experience," I feel that I may usefully draw attention to the services provided by the Central Bureau of Hospital Information, in conjunction with the British Hospitals Association.

For more than a quarter of a century the Bureau has collected and disseminated information and opinions bearing on every aspect of hospital administration, design, and equipment, and its services—with those of its honorary advisers—have always been available to anyone interested in such problems, both in this country and overseas. As an instance of its work before the war, the Building Centre Hospitals Committee was set up jointly with the Building Centre, Ltd., and in due course published schedules of requirements in the planning of hospitals which could be filled in by any hospital authority who wished to give information to architects engaged to prepare plans. This committee had perforce to lapse at the outbreak of war, but collaboration with the Building Centre has continued.

A more recent development, at the instigation of the British Hospitals Association, has been the setting up of an Advisory Committee on Hospital Equipment within the organization of the British Standards Institution. The work of this committee is likely to assume considerable importance from the point of view of hospital design as the range of equipment for which specifications are made is widened to embrace the larger types of fixture.

I do not wish to suggest that Mr. McCurrieh would necessarily find within the compass of the Bureau itself all the information for which he has been looking, for the Bureau has never claimed to be self-sufficient. It may well be, however, that it could give guidance as to where authoritative information might be found if not in its own possession, since it remains in a unique position to correlate the opinions of those interested in hospital problems today.—I am, etc.,

General Secretary of the British Hospitals Association,
21, Colindale Avenue, London, N.W.9.

J. P. WETENHALL,
Director.

Asthma and the Inhaler

SIR.—In the first years of my infancy, I have been using a bronchodilator, the inhaler, for about ten years. Not being a doctor, I am not worried by its use, but I am, however,

able to carry out a full day's work and in winter to sleep under the pillows instead of on them. I am also much less troubled by bronchitis than I used to be. Although ephedrine spray may be, as Dr. Clement Francis (Jan. 10, p. 76) states, less harmful, I find them also much less effective. Normal saline would probably be even more gentle with bronchial mucosa. If my life has been shortened by using adrenaline sprays, at least I shall have had more hours of useful activity on earth than I should otherwise have had.

To the patient the advantages of this form of therapy are (a) Saving of doctors' fee; (b) there is no dreaded injection; (c) there are no side-reactions comparable with systemic adrenaline injections and work may be resumed forthwith; (d) there is no malaise and dyspepsia, so often associated with ephedrine administered by mouth.

The disadvantages to the doctor are: (a) Loss of fees; (b) with all asthma remedies, the effect is not the same with all patients; (c) when an acute attack is fully developed, the method is uncertain and dosage unregulated. I think that bed, warmth, hot drink (especially tea and coffee), and injections of adrenaline or preparations of suprarenal and pituitary are then a safer and more reliable system of treatment. (d) In the presence of acute bronchitis the solution seems unable to pass the barrier of mucus and is usually ineffective.

I consider that any asthmatic should be given the opportunity to try out this method. He should be instructed never to wait for an attack to develop, when overdosage without relief may well be possible, but to use his spray for two or three minutes as soon as he is aware of the aura of an impending attack, he fails to abort the attack, the patient should not continue with the spray, but send for his doctor. In deference to the rhinologists and because it is wasteful, the inhalation should never be made through the nose.—I am, etc.

Ewell, Surrey.

PAUL WINGATE.

Radiological Evidence of Age

SIR.—The *Palcor News Agency* of Nov. 26, 1947, reports from Jerusalem that a youth found guilty of exploding a train was established to be over eighteen by an Army radiologist, thus making him liable to the death sentence. When his parents challenged the age and produced a recently issued birth certificate, the court queried it. The father of the accused said that until his son's capture he had not required a certificate. It was only when the aged man who had circumcised the boy on May 1, 1930, could be produced that it was established that the boy was only 17½ years of age and so not liable to the death penalty.

This case, if correctly reported, raises the serious issue of the reliability of radiological evidence of age. One wonders whether the majority of radiologists would care or dare to fix an age with certainty within six months, and, if so, on what evidence. From my knowledge of radiology I think most radiologists would hesitate to be exact even within a year. It seems that this important question has received no publicity in this country and it should not be allowed to pass without comment from the profession.—I am, etc.,

Urmston, Lancs.

BERNARD SANDLER.

Test of Death

SIR.—On reading the abstract of "Les signes de la mort absolue" (Daniel and Daniel, *Avenir méd.*, 1946, 71-5) in *Abstracts of World Medicine*, December, 1947, I was reminded of a simple procedure which I used to employ in clinical work as a confirmatory test of absolute death.

I observed that the retinal vessels took on, after death, a curious appearance. The blood column was broken up into segments of varying length, each segment ending quite abruptly and separated from the next segment by a well-defined gap. The extent of this disintegration of the blood column varied from case to case. This sign was never present when other signs of life were in evidence, and was often obtained within a very short time of their disappearance.

I am not aware that this sign has been described; it certainly does not seem to be generally taught. My series was too short to form a definite opinion, but I had the impression that the test might prove useful.—I am, etc.,

Sealand, Cheshire.

E. A. HARRIS.

Treatment of Rheumatoid Arthritis

SIR,—In connexion with my article on the above subject, published in the *Journal* of Aug. 16, 1947 (p. 252), I have received various inquiries, some of them through the correspondence columns of the *Journal*, and some of them direct. Several correspondents ask me about the necessity of blood typing. My answer is that blood typing is absolutely necessary. Moreover, cross-typing must also be carried out in order to exclude sub-groups and particularly the Rh factor, especially if the transfusion is repeated.

Other correspondents ask me for an explanation of the astonishing phenomenon that a pregnant woman's blood is able to cure some cases of rheumatoid arthritis. I purposely refrained from giving an explanation. I do not believe in guesses which are not based on positive facts. But I have, of course, pondered the problem, and my first idea—which I think must occur to everyone—was that the effect of the blood should be attributed to the multiplication of hormones during pregnancy. Everything, however, seems to contradict this hypothesis. Hormones given in a peroral and parenteral way have not achieved any result, even in strong doses; this disappointment must, I think, have been experienced by everyone. Besides, the effect of pregnant blood is not similar to the effect of the hormone. The effect of all hormones hitherto used for medical purposes has been ephemeral; it lasts only so long as the hormones circulate in the organism. When the hormones have been destroyed or excreted by the organism, which occurs very soon, their effect also ceases, and the symptoms of the disease recur. Pregnant blood, on the other hand, when its effect is favourable, starts a process of recovery which continues even if the dose is not repeated. To find an analogy, we should compare its effects rather with those of the immunization sera; and if we look for a hypothesis, I think it more probable that the foetus and its attachments create, as antigens, such antibodies in the mother's body as are able to counteract the causative agents or toxin of rheumatoid arthritis. We know of analogies for this—i.e., the Rh factor or the Weil-Felix reaction. From this point of view the globulin content of the pregnant blood should be examined.

As regards the possibility of shock, it is difficult to give a categorical answer. I can at any rate state that in my own practice I have found that pregnant blood can be effective without causing fever.—I am, etc.,

Budapest

IMRE BARSÍ

Penile Carcinoma

SIR,—With regard to this controversy, is it necessary to bring in "mixed bacterial flora of the prepuce"? In spite of our ignorance of the causes of cancer we do know that syphilis is a predisposing cause in certain situations—e.g., the tongue. The commonest site for a primary chancre in the male is the prepuce. The spirochaetes gaining entry in an abrasion or tear; that in the female is the cervix. In the circumcised the delicate mucous membrane of the glans is replaced by stratified epithelium, which is much less liable to abrasions, therefore to infection and becoming a source of infection.—I am, etc.,

Dumfries.

A. P. BERTWISTLE.

SIR,—We must get back to the fundamental facts raised by Mr. W. Sampson Handley (Nov. 22, 1947, p. 841). We either accept his contention that circumcision in the male will greatly reduce the incidence of carcinoma of the cervix, in which case we must support his plea for operation of the prepuce, or we do not, in which case evidence to the contrary should be produced. So far, his conclusions have not been seriously challenged. It is on the type of operation to be performed that I dared to differ from so distinguished a surgeon. I confess I have had no experience of fenestration operations on the prepuce of the infant, but suggest that if anything requires to be done in that region then there is a simple operation which has stood the test of time—i.e., "ritual" circumcision.

As regards the history of the operation, a slight correction requires to be made in the statement that "Abraham learnt its advantages from his Arabian wife Zipporah, who circumcised their son." Zipporah, wife of Moses, lived in a later epoch and only circumcised her son on the threat of Divine wrath. The Covenant, that in the future all males were to be cir-

cumcised on the eighth day of life, was made with Abraham, who underwent the operation at the same time as his son Ishmael. Abraham was then 99 years old (the science of geriatrics seems to have arisen later with King David and his two hot "water-bottles") and Ishmael 13 (hence, presumably, the Arab custom of circumcising at that age). The operation, therefore, may be said to have been practised by the Jews, without interruption, from the time of Abraham to the present day. I did not say they originated it but merely suggested that an element of proficiency must by now have crept into the proceedings.—I am, etc.,

London, W.1.

DAVID PREISKEL.

SIR,—In the original annotation (Nov. 1, 1947, p. 699) which started this correspondence the statement is made that "circumcision and personal hygiene are the only two prophylactic methods which are likely to reduce the incidence of carcinoma of the penis."

Most of your correspondents have advocated the first method, but surely the simpler and more aesthetically correct method is to insist on personal cleanliness. Every mother should be shown by her medical attendant how to retract the prepuce and cleanse the glans and sulci of her infant son; the son in turn being instructed by his mother. Personal cleanliness in this direction is surely just as important as brushing the teeth or washing the ears, and I have never yet heard the suggestion that the cure for dirty ears is amputation.—I am, etc.,

Ilkley, Yorks

R. JOHN GOURLAY.

D.D.T. as an Anthelmintic

SIR,—In your issue of Nov. 15, 1947 (p. 805), there is a query and a reply on the subject of D.D.T. as an anthelmintic. Some time ago I thought of the possible use of D.D.T. in treating helminth infestations and conducted a short trial of its use in patients showing ova of roundworm, hookworm, or whipworm in their stools.

I had no data available concerning the toxicity of D.D.T. in milligrammes per kilo of body weight, so after various calculations I decided on using a dose of 1 gr. (65 mg.) of pure D.D.T. powder. To test the safety of this dose I took two treatments myself first, using 2 gr. (0.13 g.) as the dose. The only symptoms arising from the D.D.T. were very slight nausea and a mild warm sensation in the epigastrium lasting about three hours and commencing about an hour after ingestion of the powder. No delayed effects were noticed.

Only patients whose stools showed heavy infestations were chosen for treatment, and all were adults, some male and some female. The following routine was employed: (1) At 20.00 hours the previous night sodii sulph. 1/2 oz. (15 g.) was given and no further food allowed. (2) At 06.00 hours D.D.T. purc. gr. 1 (65 mg.) with gr. 5 (0.32 g.) kaolin were given in a gelatin capsule. (3) At 08.00 another dose of sodii sulph. 1/2 oz. (15 g.) was given. (4) After the bowels had worked well, food was allowed. (5) The patient was kept in hospital for forty-eight hours after the treatment. (6) While in hospital all the patients' stools were collected and examined carefully for worms, the number being tabulated. (7) Two weeks later a further stool examination was done.

Results were disappointing. In a small series no roundworms or whipworms other than an odd one purged out were recovered, but with hookworm (all *A. duodenale*) death of worms did occur. However, eradication of the hookworm infestation did not occur and follow-up stool examinations were always positive. Speaking generally, I would say the effect of D.D.T. was approximately about a half to three-quarters that of tetrachlorethylene if estimations of such vagueness are permitted.

On the grounds of these early indications that D.D.T. was no good in the eradication of roundworms and whipworms, that where hookworm was concerned it was inferior to one of the cheapest effective anthelmintics, and bearing in mind the dangerous nature of the substance being used, I did not extend the experiment on more scientific lines.

If anyone else has had any experience of the therapeutic use of D.D.T. internally, I would welcome their comments on my investigations.—I am, etc.,

Kuala Belait, Borneo.

K. F. D. SWEETMAN.

The Lazy Eye

SIR.—I would like to answer Mr. S. Black's accusation (Jan. 10, p. 77) that the School Ophthalmic Service is essentially curative. Admittedly this is so in many parts of the country, but in Devon the preventive side is considered the most important. For the past ten years the Devon County Council has entrusted the Ophthalmic Service to the care of two full-time ophthalmic surgeons under the County Medical Officer. There is complete liaison between the Maternity and Child Welfare Department and the School Ophthalmic Service, and infants are seen and followed through their pre-school and school years.

Any infants suspected, even remotely, of eye defect by medical officer, health visitor, or parents are referred to the ophthalmic surgeon for full examination, and having once been referred they become the responsibility of the ophthalmic department. In this way congenital defects, squints, errors of refraction, particularly high degrees of anisometropia, are treated at an early age and the development of amblyopia prevented.

On attaining school age every child in every school has a visual acuity test every year, the most important group being that of the school entrants, who, though they are not conversant with letters, are tested by other reliable and scientific methods. Any child not attaining the standard of 6/6 in each eye separately is referred for ophthalmic examination, through which it is possible to find visual defects early so that treatment can be instituted before it is too late to be effective.

Naturally many cases referred are found to have no ophthalmic defects at all, but the principle is maintained that it is better to examine the normal than miss the defective.—I am, etc.,

Exeter.

MARGARET L. FOXWELL.

The Dangers of Going to Bed

SIR.—Dr. R. A. J. Asher's article on "The Dangers of Going to Bed" (Dec. 13, 1947, p. 967) prompts me to record the following case.

Some five years ago a middle-aged female patient was transferred to me by another surgeon who had performed a cholecystectomy on her two weeks previously. Since operation she had had a persistent, profuse biliary fistula and clay-coloured stools. I operated on her about a week later and found that the common hepatic duct had been completely divided where it emerged from the liver, the right and left hepatic ducts having united intrahepatically. A bougie was passed down the duct into the duodenum without obstruction. The divided ends were sutured together round the upper limb of a T-tube, which was inserted into the common bile duct.

About three weeks after this operation, when the amount of bile draining externally was slight, the tube was removed. Thereafter the bile loss became copious and the stools almost clay-coloured. When this had persisted for a further three weeks and the patient's condition was deteriorating, I considered that it was necessary to repair the leak, but the ward sister appealed to me to allow her to try getting the patient out of bed. I did not think this would have any effect on the fistula, but agreed that it would at least be good for "morale" in view of the impending third operation. However, within forty-eight hours of her starting to get up the fistula was dry and the stools normal. Further recovery was uneventful.

In my opinion the complete healing of the duct was prevented by being constantly bathed in a pool of bile which collected while the patient was lying in bed. Since this lesson I have not postponed getting-up choledochostomy cases until the wound was dry, and have found that this earlier ambulation accelerated complete healing of the duct.—I am, etc.,

Edinburgh.

J. P. PHILP.

SIR.—Regarding as a jocose article Dr. R. A. J. Asher's contribution (Dec. 13, 1947, p. 967) makes thoroughly enjoyable reading. "Look," he says, "at a patient lying long in bed. . . . The blood clotting in his veins, the lime draining from his bones, the sebums sticking up in his colon, the flesh rotting from his feet, the urine leaking from his distended bladder, the sweat evaporation from his soul." It is a picture worthy of Edgar Allan Poe. But Dr. Asher is pulling our legs just a little. It is not as bad as all that "really," and rest is essential in the treatment of many diseases," he admits. Under the heading "The patient in bed" I suggest going even one better than Dr. Asher, and that the tuberculous patient with a large cavity should go to bed, because nearly all fatal cases of tuberculosis occur when the patient is at rest.

Dr. Bruce Williamson (Jan. 3, p. 26) still further enlarges on the dangers of treatment by rest. He tells us that for cases of rheumatic fever "in bygone days months in bed was considered sound practice, with *mitral stenosis as the inevitable end-result*" (the italics are mine). I am not supporting too-prolonged treatment by rest after rheumatic fever, but I would like to know what scientific evidence he can adduce by way of proof that it was the rest in bed that was answerable for the mitral stenosis. To say that it is the inevitable result is putting it strongly. Can't he think of just one case out of the whole lot that escaped mitral stenosis? He also says: "If we wish to *stenose*" (again my italics) "any part of the body immobilization is the accepted procedure." Then, if we immobilize a fracture are we "stenosing" it?

Nearly fifty years ago—in those "bygone days"—it often seemed to me, as a medical student at hospital in London, that just the rest in bed was more than half the battle, especially with hard-worked East End housewives, who had never known before what real rest meant, and what it felt like to be for once waited upon, instead of doing everything oneself. But it is the evils of *overdose* (Dr. Asher's italics) with bed that Dr. Asher is tilting against, and I have little doubt Dr. Asher would agree with me here.—I am, etc.,

Southborough, Kent.

E. WEATHERHEAD.

Prickly Heat: A Simple Remedy

SIR.—With reference to Dr. C. J. Wilson's letter on the above subject (Jan. 10, p. 76) describing the use of perchloride of mercury, 1 in 500, I use a rather similar treatment which I find very effective. The following lotion is used: Biniodide of mercury and spirit, 1 in 1,000, 1 oz. (28.4 ml.), diluted with an equal quantity of water, with the addition of menthol, 10 gr. (0.65 g.). This lotion is dabbed on the affected parts after bathing and allowed to dry. A little menthol powder is then dusted on to the area. This treatment gives a marked "hot and cold" sensation which lasts about 10 minutes. One or two applications are usually sufficient to clear the condition. As a precaution I warn patients to test the treatment on a small area first before treating the whole area. Also, if they find that the lotion causes too much "burning," they may dilute the lotion with an equal part of water. I should be interested to hear the results of any cases treated with "benadryl."—I am, etc.,

Accra, Gold Coast.

M. P. BROWN.

Aetiology of Prickly Heat

SIR.—In support of Dr. C. J. Wilson's letter (Jan. 10, p. 76) regarding the use of a solution of perchloride of mercury, 1 in 500, applied locally in the treatment of prickly heat, may I confirm his findings by my own observations in the use of this drug when treating cases amongst Service personnel in Assam during the late war? In the Shurma Valley area of Assam there is during the monsoon period a high incidence of prickly heat amongst Europeans, and it was on the advice of a doctor: long residence in the district that I commenced treating cases with perchloride of mercury. In most cases this treatment led to a rapid cure comparable with the findings of Dr. Wilson. No other treatment was so effective, and it would appear that mercury when applied to the skin is a specific for this complaint.

The aetiology still remains obscure, but the fact that mercury appears so effective in treatment suggests that a mercury-sensitive organism—probably a fungus—is the cause. I would be interested to know whether research has been conducted on these lines and whether a predominating organism of this type has been isolated: obviously secondary infection with pyogenic organisms occurs. That a few isolated cases fail to respond to the above treatment suggests more than one aetiological factor.

The following observations are noted: (1) The incidence of prickly heat varied directly with the atmospheric humidity. (2) Whilst high temperatures favoured the condition—i.e., over 90° F. (32.2° C.) shade temperature—the incidence showed direct relation to the humidity rather than the temperature. (3) Europeans who habitually wore no clothing apart from loose-fitting pair of shorts during daytime were less affected. (4) The wearing of silk or closely woven cotton garments favoured the condition. (5) Loose-fitting "aertex" garments of the bush-shirt type, frequently changed, appeared to be the

COMBINED PROTECTION WITH 3 INJECTIONS

By the use of 'Wellcome' brand Diphtheria-Pertussis Prophylactic, D.P.P., children may be immunised against the two diseases in a course of three injections. The product contains Diphtheria Prophylactic A.P.T. plus Whooping Cough Vaccine (Alum Precipitated). Immunisation with 'Wellcome' Diphtheria Prophylactic A.P.T. has markedly reduced the incidence of and mortality from diphtheria. Although Whooping Cough Vaccine does not confer a degree of immunity comparable with that induced by diphtheria prophylactics, wide experience amongst clinicians indicates its value in reducing the incidence and severity of the disease.

'WELLCOME'

True Hermaphroditism

SIR,—In reply to Dr. J. R. Edisbury (Dec. 27, 1947, p. 1056), may I refer him to my *Hermaphroditos: The Human Intersex* (second edition, Heinemann, 1946), embodying my Thomas Vicary lecture of 1941? I endeavoured to demonstrate in this work that "true hermaphroditism" cannot be accepted in humans in the light of recent biological work and that this erroneous conception had infiltrated into our science from the daemonology of the ancient Eastern people, repeated naively by the Renaissance teratologists, and accepted uncritically by writers of more modern textbooks.

Only in certain lower animals is true hermaphroditism seen, but these are double animals consisting of a male and female united. They result embryologically from a parallel development of masculinizing and feminizing sex-formative genetic impulses. In higher animals sexes have separated, and in these "gonochorists" hermaphroditism is a contradiction in terms.

Such animals and man are genetically either males (XY) or females (XX), but through certain experimental conditions feminization of a genetic male or masculinization of a genetic female can be obtained. This sex reversal shows according to experimental conditions three degrees. In the first degree the intersexualization bears only on the morpho-psychological characters. In a second degree the genital organs and tract are involved. In a third degree the gonads themselves partially submit to the intersexualizing process. This corresponds to the three forms of human intersexuals. Genetic males may show feminization only of their morpho-psychological sexual features (morpho-psychological androgynoidism); others proceed to feminization of the genital organs and tract (genital androgynoidism), and others show partial feminization also of their gonads (gonadal androgynoidism). The same applies to masculinized women, or gynandroids.

Morpho-psychological androgynoidism and gynandroidism are designated feminism or virilism. Genital androgynoidism and gynandroidism are designated with the barbaric clumsy terms male or female pseudo-hermaphroditism. Gonadal androgynoidism and gynandroidism are included in "true hermaphroditism." Thus, true hermaphrodites are simply genetic males or females in whom the intersexualizing process has progressed up to the gonads. The term "true hermaphroditism," which reminds us of old daemonology, should be discarded—but daemonology dies hard.—I am, etc.,

London, W.I.

A. P. CAWADIAS.

Medical Treatment of a Sprinter

SIR,—My attention has been drawn in recent weeks to the anxiety caused by a report published in the *Evening News* (Sports Edition, Oct. 27, 1947), wherein appear my comments on the treatment of an injury sustained by Macdonald Bailey, the international sportsman, at the White City on Aug. 3, 1947. On that occasion Macdonald Bailey collapsed on the running track and was found to have injured certain muscles of the thigh.

I examined Macdonald Bailey some weeks later and understood from him that the injury had not been seen by a specialist for ten weeks and that he, Macdonald Bailey, did not realize the true nature of the injury.

My comments, referred to above, were based on this information. However, from information subsequently placed before me by professional colleagues who were then responsible for the care and treatment of Macdonald Bailey consequent upon receipt of this injury, it seems clear that the runner did receive, on return to his Air Force unit, a full medical examination by the medical officer concerned and also, within a short space, by a specialist attached to the Royal Air Force Medical Service.

I now desire to make it clear that my comments were not intended to impute, to those responsible for the care and treatment of Macdonald Bailey at the material time, any lack of professional care, and if such an interpretation has been placed upon my words as reported, then I regret it.—I am, etc.,

London, W.I.

C. R. WOODARD.

POINTS FROM LETTERS

All Resign

Dr. W. C. COLVILLE (Rowrah, Cumberland) writes: As a younger member my bias is in favour of the Act, perhaps because I stand to lose much less materially than my older well-established colleagues. After all, as has been said, we are living under a quiet revolution. I admit, Service medicine did make my faith falter with regard to regimentation. Mr. Bevan's attitude has also shaken my faith. . . . Have we any constructive suggestions? We should certainly all abide by the majority result on the plebiscite. . . . If there is an overwhelming majority all concerned should resign from the N.H.I. in April next and let the public know why the doctors are resigning. That would leave private practice only, just as in the good old days—payment for work done—and give the public three months to help the Minister of Health to come to his senses as far as negotiation is concerned. Strong words need strong action as well. If the Act is to be amended I make the following additional suggestions. Night work should receive additional remuneration. This will act as a material palliative. It will also open the way for a rota system, for the doctor on night call will get extra payment for his night shift.

If the capitation system is to succeed, the public should be charged —e.g., as a fine—if they have been living in the area for over six weeks and yet haven't got themselves on a doctor's list. There is nothing more exasperating than a panel patient rolling up with his card the first time he is ill and yet he has been living in the area for months. . . .

N.H.S. and Reality

Drs. C. E. BIGGER and DOROTHY L. BIGGER (Birmingham) write: (1) Those thousands who never go near a doctor now because the chemist is cheaper will be able to get their bottle of aspirins, etc., from the doctor—free. (2) The mother of every baby in the country will come to the doctor for syrup of figs or milk of magnesia—free. (3) Those who now attend the welfare clinic will get their own doctor's advice—free. (4) Doctors will have to get a permit before they can do midwifery. If they are foolish enough to do so, they will find that every pregnant woman in the district will elect to have a doctor, even for her eighth—free. (5) There will only be the same number of doctors to do three or four times the work. What chance will the patient who is genuinely ill have of getting a better service when the doctor is swamped by the "Something for Nothing" brigade?

Trying the N.H.S.

Dr. T. MILLER (Trimdon Station, Co. Durham) writes: On reading Dr. William Parker's letter (Jan. 17, p. 119) I had a feeling of indignation. "The Minister states he is not prepared to alter the Act before the new Service has been tested. . . ." So Dr. Parker wishes to have it tried out in N. Ireland. Does Dr. Parker know that N. Ireland will have a new service of its own which I think would be welcomed by the majority of doctors here? . . . After all, the people of N. Ireland have their own government capable of forming a Health Bill in accordance with the wish of the people. . . .

Penile Carcinoma

Mr. W. SIMPSON HANDLEY writes: Dr. I. Gottlieb (Jan. 10, p. 79) quite rightly sends me to the bottom of the class in Biblical history. Ziporah was the wife of Moses, not of Abraham, and I am indebted to Dr. Gottlieb for his courteous correction of my error. I think, however, that my main conclusion remains unaffected. Circumcision is specifically Jewish only as a ceremonial rite. As a hygienic practice many races inhabiting hot climates had independently realized its advantages.

Post-operative Scar

Dr. R. S. CAREY (Brislington, Bristol) writes: Having recently undergone a major abdominal operation involving a long vertical scar, I would like to suggest to surgeons that such cases should be nursed, where possible, with the spine in an overextended position for the first few days. In the usual sitting-up position the abdominal wall tends to crumple, with the result that the healing scar is from one to two inches shorter than it should be. Stretching this after the patient is allowed to get up is a painful proceeding and inevitably delays full ability to stand erect. Incidentally, the extended position gives more room in the thorax and should aid in preventing hypostasis in the lungs.

Under the National Health Service Act the property of hospitals will be transferred to the Minister of Health on the appointed day. A circular has therefore been sent from the Ministry of Health to voluntary teaching hospitals requesting a return listing all the properties and interests specified in the circular, irrespective of their destination on the appointed day.

Obituary

Dr. **FREDERICK JOHN CARLYLE JOHNSTONE** died in King's College Hospital, London, on Dec. 20, 1947, at the age of 54. He had been flown to England from Kenya only a few weeks previously, and to his colleagues and friends there the news that he was seriously ill and might not recover had come as a shock. Dr. Johnstone was born in 1893 in Melrose, where his father was the medical superintendent of one of the largest mental hospitals in Scotland. He was educated at St. Mary's School, Melrose; at Edinburgh Academy; and at the University of Edinburgh, where he graduated M.B., Ch.B. in 1916, proceeding M.D. in 1920 and taking the D.P.H. in the same year. He obtained the Liverpool D.T.M. in 1924. On the outbreak of war in 1914 he received a commission in the Royal Field Artillery, with which he served as a combatant officer in France and Salonika till 1916, when he was recalled to complete his medical studies. On graduating he was appointed to the R.A.M.C. and sailed towards the end of that year for East Africa, where he served until the end of the war, being mentioned in Van Deventer's dispatches. He also took part in the Turkana Expedition of 1918-19. He went out to Kenya as a medical officer early in 1921. He was promoted senior health officer in 1926, and deputy director of medical services in 1933, serving in the Kenya Medical Department until 1944, when he was transferred to the Gold Coast on promotion to the post of D.M.S. in that colony. Invalided from the Colonial Medical Service about a year later he returned to Kenya, free at last to make farming, which had always been his hobby, his life's work. Throughout his service in Kenya, Johnstone was an outstanding personality, and though his contributions to medical literature were few, his contribution to medical thought on the health problems of Kenya was large. He inspired and influenced not only his medical friends but his colleagues in the administration. On arrival in Kenya he was posted to the large native reserve of Central Kavirondo in the Nyanza Province, where, as he had no hospital, he was almost continuously on safari. He gained the confidence of the Luo people to a remarkable degree, and on his own initiative was responsible for what was probably the first biological survey of a native tribe ever carried out in East Africa. The data which he then obtained were of inestimable value and provided for the first time a sound basis for the formulation of policies for the promotion of the people's health in the native reserves and, indeed, outside them. He was also a pioneer in the matter of improved African housing and was responsible for the erection of the first model village buildings in Kenya. Johnstone was a first-class administrator, an excellent judge and manager of men, and the most loyal of colleagues. Apart altogether from his efficiency and enthusiasm in the field of public health, he will long be remembered for his bluff heartiness, his hospitality, his cheery friendliness, and his most eagerly proffered helpfulness wherever help was required. To his family we offer our sympathy in their great loss—A. R. P.

Dr. **HERRERT RAMSDEN**, of Saddleworth, Yorks, died on Dec. 23, 1947, aged 82 years, after a short illness. He received his medical education at Owens College, qualifying L.S.A., M.R.C.S., and L.R.C.P. in 1889. He graduated M.B., B.Ch. at Manchester in 1890, and took the London M.B. in 1892, proceeding M.D. in 1894. In 1899 he obtained the D.P.H. After serving as house-physician at Manchester Royal Infirmary he joined his father, Dr. W. H. F. Ramsden, in medical practice in Saddleworth. He was medical officer of health for the urban district of Saddleworth for thirty-four years, and was also certifying factory surgeon and medical officer for the Post Office for many years. He was always keenly interested in the work of the St. John Ambulance Association, of which he was an honorary life member. He was also a member of the British Medical Association for forty-three years. In spite of the heavy work of a busy and scattered practice his interests were not confined to medicine. He had been J.P. for many years and was a member of the Manchester Literary and Philosophical Society. A keen botanist, he also took the greatest interest in the study of molecular physics.—W. P. B. S.

Dr. **HENRY WILLIAM LATHAM** died suddenly, at the age of 54, on Dec. 24, 1947, at home in London, N.7. He was the last surviving member of a family of seven brothers who were all doctors. As a first assistant at the London Hospital, he qualified in 1900. He was then posted to St. Helier Road in West London, where he remained for many years and was a member of the British Medical Association for many years and was a J.P. for many years.—W. P. B. S.

Dr. **WILLIAM RIDDOCK MCLINDEN** died on Jan. 3 at his home in Oldham at the age of 53. He was born in Glasgow and educated at Glasgow University, where he graduated M.B., Ch.B. in 1918. Immediately after qualifying he served in the R.A.M.C. in Italy and was honoured by the Italian Government for his services. After demobilization he practised for a short time in Scotland and finally settled in Oldham in 1922. He was first of all the assistant and later the partner of Dr. Low, and took over the practice when his principal retired just before the recent war. At the same time Dr. McLinden became the examining factory surgeon for Oldham East. During the war he was medical officer to one of the first-aid posts, and afterwards his failing health made it necessary for him to give up part of the practice and devote himself only to those patients who were within easy reach of his home in Ripponden Road. At the time of his death he was president-elect of the Oldham Medical Society and he had been secretary of the Local Medical and Panel Committees. He was also an active member of the British Medical Association. Dr. McLinden had many hobbies, and he was particularly fond of gardening and of music. He was of a retiring disposition, but during his long period of general practice in Oldham he made many friends, all of whom mourn his death and extend their sympathies to his widow and his daughter.—W. B.

Dr. **JOHN MCMILLAN** died at his home in Shotts, Lanarkshire, on Jan. 4 at the age of 78. He was a student of Glasgow University, where he graduated M.B., Ch.B. in 1899. He saw service in the Boer War and held two assistantships before settling in Shotts in 1902. Ten years later he was appointed visiting physician to Shotts Sanatorium. His wife, who died in 1944, was matron of the hospital for eight years before their marriage. In the 1914-18 war Dr. McMillan served on the recruiting board at Motherwell, and during the recent war acted as its chairman. He was chairman of the County of Lanark Panel Committee for over ten years and a J.P. for the county. He had been an active member of the British Medical Association for many years and was chairman of the Lanarkshire Division in 1940-1. He retired in 1942 after forty years in general practice in Shotts.

J. A. M. H. writes: I wish to pay a tribute to the memory of Dr. John McMillan. He was of the old school, and relied more on his five senses than on modern instruments and laboratory methods. He had a strong constitution, and thought nothing of doing eighty visits a day in addition to his surgeries. In the early days he spent many hours, mostly at night, at confinements, often assisted only by the woman next door. His scanty leisure hours were devoted to gardening and reading. He was a good raconteur and had many an interesting tale to relate, especially of his experiences as a civil surgeon in the Boer War. Dr. McMillan was a man of high character, but with decided views. In close association with him during the past twenty-six years, I do not remember ever hearing him say ill of anyone. In my mind's eye I can see him yet, standing at the high desk in his surgery prescribing to his patients not only medicine but also sound advice in his customary calm, capable, and cautious manner.

Dr. **ALEXANDER BENJAMIN STICH** died from coronary thrombosis on Jan. 6 at the Kent County Hospital. Dr. Stich, who was 59, was educated at Paisley Grammar School and Barbour Academy. He graduated B.Sc. at Glasgow University, and for a few years acted as chief chemist to a firm of brewers. He went back to the University in 1913 and took the M.B., Ch.B. in 1918. He acted as a house-surgeon at the Royal Maternity Hospital in Glasgow, and later as R.M.O. at Smithson Asylum, Greenock. He then went into general practice in Co. Durham, in partnership with Dr. N. Davie. He remained there for sixteen years, during which time he took an active interest in the work of the British Medical Association. He was chairman of the Gateshead Division in 1929; a representative at annual representative meetings for ten years; and he also served on the Panel Committee for more than fourteen years, finally as vice-chairman. He was later in practice at Spray Hill, Lamberhurst, Kent, retiring only in 1947 when ill-health made it impossible for him to continue.

Dr. **WILLIAM CHARLES WATSON GLENNY** died on Jan. 7 at his home at Warrenpoint, Co. Down, at the age of 72, following a prolonged illness. He was the eldest son of the late Rev. Robert Edmund Glenny, Rector of Clonallan, Warrenpoint, and was educated at St. Bee's School, Westmorland, and the College of Surgeons, Dublin. He served in the South African War and wrote a book about it, and was a captain in the R.A.M.C. in the 1914-18 war. About the beginning of the

century he went into private practice at Omeath, Co. Louth, where he was a J.P. for the county, and later went to reside in Warrenpoint, on the other side of Carlingford Lough, where he received a similar honour. He held high office in the Masonic Order, and in the Church of Ireland. Dr. Glenny was well-known and loved throughout the countryside for his unsparring care of those who sought his help, help often given while he himself was suffering acute pain. Unable to get about in his later years, he retired in 1939, and was succeeded by his nephew, Dr. Rex Glenny. He is survived by his widow and four brothers, one of whom is a surgeon in Singapore, and three sisters.—R. G.

Dr. FRANCIS WILLIAM CHANDLER died in a nursing home in Sidmouth, at the age of 79, on Jan. 7. As a student at University College Hospital he was well known as a boxer, and before graduating in 1908 he travelled abroad for some years. He sailed before the mast round Cape Horn, and he spent some time as a cowboy in America. He went into general practice in Woodseats, near Sheffield, in 1911, and there he remained until his retirement in 1945.

Dr. JOSEPH BARCROFT ANDERSON died in Dublin on Jan. 10. He was educated at Trinity College, Dublin, and at Guy's Hospital, graduating in 1892 and proceeding M.D. in 1897. He took the Cambridge D.P.H. in 1901, and he was also a barrister-at-law. Dr. Anderson went out to South Africa to take up a Government appointment in 1901. He was an advocate in the Supreme Court of the Cape Province Division of the Union of South Africa, and he represented the South African Branches on the Council of the British Medical Association in 1925-8, during which time he also served on the Dominions Committee. Towards the end of his life Dr. Anderson became increasingly interested in the study of Hebrew, Greek, and Assyrian, all of which languages he used in a commentary on the Old Testament which he was preparing. It was largely in order to further his knowledge of Assyrian cuneiform characters that he returned to this country in 1947 so that he might work at the British Museum.

Dr. JOHN LEWIS THOMAS died recently at his home in Brynmawr, Breconshire, at the age of 85. Even when he had reached his eightieth year Dr. Thomas was able to deputize for some of his former medical colleagues in order that they might have a holiday. For the last few years he had been confined to bed and had suffered much discomfort and pain, but bore it patiently and courageously. His father was one of the pioneers of local government in Breconshire during the last century, and Dr. Thomas was the first pupil to be enrolled at Lewis School, Pengam. From there he went to the University College of Wales, Aberystwyth, winning at the early age of 15 one of the first exhibitions to the College. From Aberystwyth he went to St. Bartholomew's Hospital, where he qualified in 1887. The first permanent post Dr. Thomas had was with the International Navigation Colliery, Blaengarw. In those days the colliery doctor received little assistance in dealing with his problems. There was no local hospital in which serious injuries could be treated. The doctor had to be a capable surgeon, a skilled obstetrician, and a well-informed physician if he was to gain the confidence of his patients and keep it. That Dr. Thomas achieved this in full measure was proved by the high testimony paid to his services when he left Blaengarw to become M.O.H. to the Brynmawr, Nantyglo and Blaina Urban District Councils and to continue general practice in his home town. In 1912 Dr. Thomas proceeded M.D. at the University of Durham. From 1914 to 1931 he was one of the physicians of the Welsh National Memorial Association. Dr. Thomas was a capable doctor and a great personality. Up to the last few months of his life he was a constant reader of the most recent medical volumes and was conversant with modern movements in surgery and medicine. But he combined thoroughness with versatility and was a first-rate clinician. He was in advance of the majority of his colleagues in appreciating the importance of social and industrial conditions in preventive medicine. Throughout his life he was a voluminous reader of current literature, history, and books on religious subjects. His friends will long treasure memories of many of his talks, especially when he was in a reminiscent mood. Like his father, he used words sparingly, his phrases were picturesque, and a kindly humour pervaded his talk. He published some delightful sketches of the quaint personalities who lived in the Brynmawr district when he was young. After many years of happiness together, his wife, Mary, died a few years ago. Her great charm and unflinching generosity endeared her to many friends and to large numbers of her husband's patients.—E. O. L.

Medico-Legal

CONTRACEPTIVES AND CONSUMMATION

[FROM OUR MEDICO-LEGAL CORRESPONDENT]

Up to 1857 the usual procedure for obtaining a declaration of nullity of a marriage was to bring suit before the Ecclesiastical Courts, and a decree could be obtained on proof of incapacity of one of the partners to consummate the marriage. The jurisdiction of these courts was taken over under the Matrimonial Causes Act, 1857, by the High Court, and this Act provided that the principles applied by the former courts should still be observed in such cases. In 1913 it was decided by Sir Samuel Evans in the case of *Dickinson v. Dickinson* that the wilful and persistent refusal of a wife to consummate the marriage was sufficient ground for a declaration of nullity, but this decision was overruled by the Court of Appeal in the case of *Napier v. Napier* on the ground that this would be going beyond the limits allowed in the Ecclesiastical Courts. It was felt, however, that the position was unsatisfactory, and the Royal Commission on Divorce, presided over by Lord Gorell, recommended in 1912 that such wilful refusal ought to be allowed as a ground for annulment of the marriage. It was not until 1937 that this recommendation was given legal effect in the Matrimonial Causes Act of that year—the "Herbert Act."

The question of the use of contraceptives was raised in several unreported cases in the Divorce Court during the next few years. In one such case (mentioned by Mr. William Lacey in the course of an address to the Medico-Legal Society¹) heard in 1941 a husband petitioned for nullity on the ground that his wife insisted on his using a sheath, which he did against his own inclinations. Mr. Justice Langton was disposed to grant a decree of nullity on these grounds, but felt bound to accept the wife's evidence that there had in fact been complete intercourse without any contraceptive. Four years later the same plea was raised in the case of *Cowen v. Cowen*, when the Court of Appeal decided that insistence by one partner on the use of contraceptives against the wish of the other partner defeated one of the fundamental purposes of marriage—namely, the procreation of children—and hence afforded proper grounds for a declaration of nullity for non-consummation of marriage.

This decision has now been declared wrong in law by the House of Lords in the case of *Baxter v. Baxter*. In this case the husband petitioned for a decree of nullity on the ground that his wife insisted, against his will, on the use of a contraceptive; he declared that during the ten years of their married life he had persistently pleaded in vain for the abandonment of this device. His petition failed in the court of first instance, which was not satisfied that he had not in fact acquiesced, albeit unwillingly, in this practice. In the Court of Appeal a similar result followed. Both these courts were, of course, bound by the decision in *Cowen v. Cowen* to give the desired relief to the husband if he had been able to establish his plea of non-acquiescence, but they came to the conclusion that a reluctant acquiescence was nevertheless an acquiescence, and so disentitled him to a decree.

The House of Lords, with that refreshing habit it has so often displayed of going straight to the root of the matter, examined the nature of the marriage contract, and decided that the procreation of children was not in fact an essential part of that contract—indeed, in many marriages there can be no possibility of offspring. The Lord Chancellor quoted with approval the words used by Lord Stair in his *Institutions*, published in 1681:

"So then it is not the consent to marry; as it relateth to the procreation of children, that is requisite; for it may consist, though the woman be far beyond that date; but it is the consent, whereby ariseth the conjugal society which may have the conjunction of bodies as well as of minds; as the general end of the constitution of marriage is the solace and satisfaction of man."

The Lord Chancellor recalled that long before the passing of the Herbert Act in 1937 the practice of contraception had become widespread and that young married people often had

recourse to birth control clinics for advice on the founding of a family. When, therefore, the legislature passed that Act, including its references to consummation, it must be presumed that Parliament had it in mind that contraceptives were in common use by married persons. It would therefore not be proper to hold that a marriage had not been consummated merely on the ground that such intercourse as had taken place had involved the use of such appliances.

This decision appears to have caused some perturbation, as judged by a number of letters to the Press in which the fear is expressed that it detracts from the sanctity of the marriage contract in this Christian country. The procreation of children is certainly given prominence in the Prayer Book as one of the chief aims of marriage, but—as has been pointed out by more than one correspondent—the Prayer Book is concerned with theology rather than law. Perhaps a more cogent criticism is that if the parties enter matrimony with the avowed desire to have children, and one partner then refuses to do so, there is a breach of contract, which ought by rights to imply a release of the other partner from any obligations involved in the marriage. However, this would no doubt have the effect of reducing marriage simply to an affair in which the partners are alone concerned, whereas of course it must always be more than this—the State is vitally concerned, too, in a contract which normally has such far-reaching social consequences.

Medical Notes in Parliament

THE APPOINTED DAY

The Minister of National Insurance, Mr. James Griffiths, has made two orders under the National Insurance Act, 1946, and the National Insurance (Industrial Injuries) Act, 1946, which fix the "appointed day" on which both Acts come into operation. In each case the orders were made on Jan. 13, laid before Parliament on Jan. 20, and came into operation on Jan. 23. The appointed day for all purposes of both Acts will be "the fifth day of July, 1948." The new National Insurance Scheme will thus come fully into operation on July 5, and the present National Health, Unemployment Insurance, Contributory Pensions, and Workmen's Compensation Acts will at the same time be repealed. An Order-in-Council made on Jan. 26 also prescribes July 5 as the "appointed day" for the National Health Service Act, 1946.

The 4,000 Limit

On Jan. 20 Sir ERNEST GRAHAM-LITTLE asked whether Mr. BEVAN knew that the average number of panel patients on an individual doctor's list under the conditions of the National Insurance Act was 1,000 and the regulation limit 2,500; that his proposal circulated to all medical practitioners that the number of patients allowed to any one doctor under the Act could be expanded to 4,000, while the practitioner was also allowed to take private practice, would make it impossible to give any proper attention to patients; and what consultations he had before making this proposal.

Mr. BEVAN said the figures quoted did not include dependants of insured people or private practice. Sir Ernest would be reassured to know that the figure of 4,000 was accepted by the Negotiating Committee of the profession.

U.S. and Canadian Qualifications

Asked on Jan. 21 to what extent or under what circumstances colonial medical practitioners trained in the U.S.A. and Canada might practise in British colonies, Mr. REES-WILLIAMS replied that in the United Kingdom with regard to the registration of practitioners obtained in the U.S.A. and Canada, certain conditions of registration were registrable by the General Medical Council, but there was no reciprocity between the U.S.A. and the United Kingdom, and the U.S.A. qualifications were registrable in the United Kingdom in the legislation of some Colonies. He said that the Medical Council of the United Kingdom did not know of any reason why Colonial practitioners should not continue to follow the

practice of the General Medical Council, but he was considering, in consultation with the Governments concerned, the possibility of special temporary arrangements being made to permit the registration of doctors who, because of the war, studied in North America instead of in the United Kingdom, provided that their qualifications were satisfactory. Mr. REES-WILLIAMS added that it was as important for the public in the Colonies to be protected as for the public in the United Kingdom.

Obstetric Analgesia.—On Jan. 22 Mr. SORESENSEN asked for the approximate cost of simple analgesic apparatus as compared with other apparatus for a similar purpose and to what extent specialists in his department had considered the respective merits of different methods of whole or partial anaesthesia in confinement. Mr. BEVAN said he was not clear what comparison Mr. Sorensen had in mind. Portable apparatus approved for use by midwives cost £20 to £25. Midwives used apparatus and methods approved by the Central Midwives Board on the advice of the Royal College of Obstetricians and Gynaecologists. Production and distribution of apparatus were satisfactory, and 220 institutions had been approved for training.

Blood Donors.—Colonel STODDARD-SCOTT, on Jan. 22, asserted that many hospitals found it increasingly difficult to obtain blood donors for blood transfusion services. Mr. BEVAN said that apart from isolated cases he was not aware that hospitals experienced difficulty in meeting their needs. In the first three quarters of 1947 the estimated effective strength of donor panels rose by nearly 40%, from 267,000 to 369,000, and the response of donors to calls rose from 36% to 41%.

Patients Going Abroad.—Sir WALDRON SMITHERS reported on Jan. 22 that British tuberculous patients in sanatoria abroad were required to submit two doctors' certificates, a full-size x-ray plate and the sum of four guineas every three months in order to apply for funds to continue their treatment. Mr. BEVAN said he was not aware of these difficulties, but would look into the position.

Universities and Colleges

UNIVERSITY OF CAMBRIDGE

Wing Commander R. H. Winfield, D.F.C., A.F.C., M.B., B.Ch. R.A.F., will deliver a course of three lectures on "Some Effects of Polar Conditions on Man" in the Scott Polar Research Institute of the University on Fridays, Jan. 30 and Feb. 13 and 27, at 5 p.m. The lectures are intended primarily for medical students but are open to all who are interested. Admission is by ticket, which may be obtained, without fee, from the institute.

UNIVERSITY OF ST. ANDREWS

The following candidates have been approved at the examination indicated:

M.B., Ch.B.—M. S. Boyd, Herta Braunova, I. A. Campbell, Margaret Dougall, W. B. M. Howie, I. R. Lindsay, E. M. Little, R. A. Maxwell, Robert Soutter, Moyra R. Treasure, J. E. H. Tullis.

UNIVERSITY OF GLASGOW

At a ceremony of graduation held on Jan. 10 the following medical degrees were conferred:

M.D.—J. T. N. Fraser, W. A. Parker, A. H. Imrie, N. R. Cowan, T. J. Cowie, W. P. D. Logan, Eileen S. M. Wybar, J. Berkeley, R. J. Gentry, D. N. Ross.

M.B., Ch.B.—Joan M. S. Armstrong, J. B. Brennan, A. G. Chrysides, A. I. Craig, M. B. L. Craigmyte, J. M. Cuthill, D. E. Donald, J. A. Ferguson, A. Garven, I. MacD. Hall, J. Harper, J. S. H. Inglis, J. W. Junor, R. E. Margaret M. Kerr, D. G. Landells, A. McCawley, K. McCreath, A. McDuff, R. L. McGhie, R. W. L. McLeish, M. C. Macnaughton, R. Mathison, F. Meichen, Elizabeth McG. Miller, Mary S. Mowat, Christine L. H. Nisbet, J. P. Ommer, D. H. Paterson, I. T. Patrick, J. J. Pollock, D. C. T. Ryle, J. A. W. Reid, J. F. Robertson, J. W. Scott, M. Shearer, Joan M. S. Smith, D. A. Smith, Jean M. Struthers, D. R. H. Urquhart, J. G. Walker, H. W. White, Joan A. S. Wilson.

¹ With honours. ² With high commendation. ³ With commendation.

UNIVERSITY OF LONDON

Bruce Arnold Dunbar Stocker, M.D., has been appointed Demonstrator in the Department of Bacteriology of the London School of Hygiene and Tropical Medicine.

The following candidates have been approved at the examination indicated:

M.S.—*French III (Ophthalmology)*: P. N. Banaji, J. H. Dobree, Ph.D. (Faculty of Medicine)—R. H. Thorp.

UNIVERSITY OF WALES

The following candidates at the Welsh National School of Medicine have satisfied the examiners at the examination indicated:

D.P.H.—E. B. Meyrick, E. C. Powell, I. M. Watkins.

QUEEN'S UNIVERSITY, BELFAST

Alan Carruth Stevenson, M.D., M.R.C.P., D.P.H., Reader in Public Health in the University of London at the London School of Hygiene and Tropical Medicine, has been appointed to the newly created Chair of Social and Preventive Medicine in Queen's University.

John Edgar Morison, M.D., lecturer in morbid anatomy, has been appointed Lecturer in Pathology.

At a Graduation Ceremony held on Dec. 19, 1947, the following medical degrees were conferred:

M.D.—G. T. C. Hamilton, *R. F. L. Logan, *Agnes J. A. Maybin, A. S. Boyd, V. G. F. Gibson, D. G. F. Harriman, J. Lightbody, Joan B. T. Logan, T. C. T. McFetridge, Kathleen G. McKee, I. B. Millar, T. S. Wilson.
